Probably the largest field of use will be in the technical and engineering fields, where it already has a foothold. As absolute non-conductors, glass plates for storage batteries will give longer life than present-day plates. For insulation, the use of spun glass thread can be used. As an example of its non-conductivity, power house workers have had their shoes bottomed with spun glass plates, to avoid shock. For the filtration of acids, glass plates are excellent.
Why Airplanes Don’t Fear Anti-Aircraft Guns

Contrary to general opinion the enemy’s aircraft when they come to view, are not really to be considered as one of the arms of the enemy artillery, but rather as one of its eyes. In fighting the enemy aircraft, our guns fight the artillery of the enemy in its most vital part. When the artilleryman succeeds in landing a hit on an enemy airplane, he performs a most important service for his fellow fighting men, for not only does he bring down the ‘plane which may be loaded with bombs, or else fitted with machine guns for attacking ‘planes and troops at close range, but further, he is helping to render the artillery of the enemy practically useless by “blinding” it. The artillery airplane, first and last, is to a large extent, an agent of aerial observation. Without this wonderful far-seeing arm of the artillery, neither side can ever hope to accomplish any of the remarkable long range big gun hits that have been accomplished. An American army officer, recently returned from France, stated that on one occasion he saw a very remarkable long range artillery fire in which three eight-inch shells landed squarely on the target eight miles away, thanks to the range corrections transmitted via wireless, from the observation airplane. The first shot fell a little past the bridge, the second shot fell a little short of the bridge, while the third one fell squarely on the target. Such work as this is being duplicated every day on the Western Front by the remarkable means of communication and observation now mustered together by the able Allied commanders.

This gives at least a slight idea of the great importance of bringing down enemy aircraft whenever possible. One way of course, is to send aloft other battle ‘planes to destroy the enemy aircraft if possible. The problem of anti-aircraft firing has always been with us, and Lieut. Colonel X. Reille of the French army recently gave an interesting discussion on this highly important problem, before the Washington Academy of Sciences. What a difficult job it is to hit a ‘plane while in flight can best be judged by those who have tried to shoot a bird on the wing, especially when the object of your sight is a considerable distance away. Also the birdmen of today have an unkind habit of looping the loop, taking a nose dive, or executing some other rapidly changing figure in the air, just about the time you get ready to plant your second or third anti-aircraft shell squarely on them. As Colonel Reille points out—‘Anti-aircraft firing does not consist merely in firing at an aerial target, but in firing at an aerial target in motion. Moreover, this target moves with a speed which cannot be regarded as negligible with reference to the speed of the projectile designed to strike it. An observation airplane with an average wind will attain a speed of 35 meters, or 3813 yards per second.” These observation machines invariably fly at an altitude of fifteen thousand to eighteen thousand feet, and it is common for excellent photographs to be taken at this altitude also. At ordinary firing ranges, the time of flight of the projectile shooting skyward amounts to about twenty seconds. Hence, under normal conditions, the distance covered by the enemy ‘plane between the moment at which the projectile is fired at it, and the moment at which it bursts in the vicinity of the target, is about seven (Continued on page 494)
How Submarines Cut Thru Nets

W e often hear heated discussions among the pro-war enthusiasts as to how a submarine war vessel can cut its way thru one or a series of steel nets. We have had ample evidence in the past few years that it is possible for such an under-water craft to borrow its way thru steel nets, no matter how fine the mesh may be, or how heavy the cables of which the nets are constructed. You will hear some people argue about "submarine net-cutters," and when they are asked to just how the "sub" manages to cut thru the net, especially when running blind, you will invariably hear a reply something like—"I do not know the exact details, but it is very easy." But is it?

Oscar A. Youngren, of New York City, has recently taken out a patent on a submarine net and cable-cutting attachment which is illustrated in action herewith. It is simple and rugged in design, and is operated by means of an electric motor placed either inside or outside of the submarine hull.

How can we locate the nets? By observations in the vicinity of such nets before totally submerging; by sinking to the bed of the harbor or channel, if it is not too deep, and liberating a diver from a special chamber provided for the purpose, who can explore the water in the vicinity of the submarine; also the proximity of nets will be made known when the submarine bumps against one, for they are usually strong enough to prevent the submarine from getting any headway once it runs into them, by clever maneuvering of the sub-sea craft and by starting up the net-cutter motors, when this condition arises, the under-sea demon can shortly hack its way thru the net.

The net-cutters themselves are made on the principle of the well-known mowing machine, which carries a long fixed toothed blade over which a second movable toothed blade of similar pitch slides back and forth rapidly. In the design here shown, an electric motor drives a reciprocating cutting rod thru a set of gears, this cutting rod being joined to a vertical reciprocating shaft which slides up and down in a water-tight tube. The upper end of this shaft connects thru a link with a horizontal rod as shown, which in turn connects with a second link fastened to the moving toothed blade. The stationary toothed blade is secured to the hull of the submarine. The horizontal connecting rod is pivoted on the point indicated in the diagram, so that as the motor-driven piston moves up and down, the movable teeth are caused to rapidly oscillate up and down. These teeth are made of tempered steel and of considerable thickness, and not only this, but they are driven with considerable force owing to the manner in which movement is communicated to them thru the pivoted connecting rod and motor gear.

GROWTHS COVER PORTO RICO WIRES.

Some years ago the telephone and power companies operating down in the southwestern part of the United States and in Mexico found that they had to replace all their wooden poles by steel ones. All for the very good reason that in that part of the country there was a very busy little bird that persisted in picking the wooden poles full of holes, honeycomb them in fact. Now we have a photo of what happens to the aerial telegraph and telephone lines in the tropical land of Porto Rico. Here aerial plant life insists in living on the wires.
Americal birdmen will soon be able to fly across the United States, thanks to the recent announcement authorized by the War Department that a chain of landing fields for air pilots is being built across the continent. In a few states they already wait the flyers, being established at intervals of 100 miles.

When completed, these well-marked, safe landing places will be to air pilots like water tanks to locomotive engineers or harbors to mariners. Besides oil and gas, the majority of the fields will supply to the pilots shelter and limited machine shop facilities, maps, charts, and barometer and thermometer ratings. New York, Pennsylvania, Ohio, Illinois, the District of Columbia, Georgia, Texas, and California already have established lines of such landing fields. Arkansas, Mississippi, Alabama, New Mexico, and Nebraska will soon be equipped.

The value of permanent landing fields, sufficiently close together to establish well-defined air routes across country, was emphasized early in the training of American flyers. Flying by compass has now become an established practice, but landing fields, like beacon lights, help the pilot to pick out his course, even tho he has a compass. Most of the landings today are on army fields.

Reports to the Division of Military Aeronautics from field officers say that this movement, like that which started good roads, is rapidly gaining momentum. It is predicted that before another year an aviator with a plane of moderate power will be able to make a transcontinental flight without difficulty or inconvenience.

A typical aerial landing field of a type already successfully used in England is illustrated herewith. This layout includes four powerful electric searchlight markers, (Mineola) having, say, two red identification beams, Philadelphia, two blue beams, etc. Another scheme would be to use a searchlight signal shutter on all the markers and to periodically blink the shafts of light on and off to give the telegraphic dots and dashes of the landing field's initials—such as N.Y. for New York, etc. This could be done by automatic switching means actuated by a time-clock at periods of 5 or 10 minutes. It would also be possible in this way to signal by short and long flashes, corresponding to the dots and dashes of the telegraph code, the condition of the field, such as dry, muddy, wet, etc. This information is of distinct importance to the aviator intending to land on the field, as the airplane is handled differently for each condition of the field. The landing dive angle varies for wet, muddy, and dry fields, as does also the position of the plane just before it lands on the field. All army and navy birdmen have to know the telegraph and radio codes so no difficulty is encountered on this score. The electric lantern atop the Metropolitan Tower in New York City has been seen to beat the time at night at a distance of 30 miles easily, with the naked eye, and at much greater distance with binoculars or field glasses.

For night flying airplanes now carry a powerful electric headlight for use in landing, and have out-board marking lights, as well as a tail light, all of which are especially needed in formation flying, where as many as 15 to 20 planes, or more, often fly in a "V" or other formation. As the airplane heads down toward the field it is supposed, in this layout of signal lights, to light on the illuminated "Potts Arrow", then taxi along until the illuminated crescent is reached. From here the plane is run off to the right or left to the hangars. A red "limit" light marks the end of the field. A meteorological observatory will be erected at certain fields. The "Potts Arrow" and other marker lights are illuminated by electric lights sunk in pits in the ground. These are covered with wired glass about two inches thick, over which the "planes can run. The arrow is red, the crescent blue.

**GERMAN "CARRY-ON MAGNET" IS TEN POUNDS OF BACON.**

A "carry-on magnet, efficacy guaranteed," was advertised recently in German newspapers by its "inventor." The magnet was declared to have mystic powers enabling its possessor more easily to endure the food privations of the country.

The price was 300 marks and the buyer was privileged to inspect the magnet before paying. Those who sent in orders received a package bearing the inscription: "Contents: One Carry-On Magnet."

It is not on record that any one refused to pay for it, for the "magnet" proved to be ten pounds of Thuringian bacon. The ingenious "inventor" now is being sought by the police.
MANY years ago, when our forefathers were fighting hard to settle the country we are now living in, their enemies, the Indians, made use of many clever schemes for communicating intelligence from one tribe to another, even over considerable distances. It is said that the Indians transmitted intelligence over distances of fifteen to twenty miles when necessary, and one of the systems by which they communicated with one another when on the war-path, was to approach of men on horseback by placing the ear to the ground and listening for the sounds of the horses' hoofs, even when many miles away.

Acting on this very idea, it has remained for an American inventor, Professor Reginald A. Fessenden, to invent a system of transmitting and receiving powerful sound waves thru the earth or water. Professor Fessenden, as generally known, is the inventor of a system of submarine telegraphy which employs sound waves for the trans-

For telegraphy, use is made of an alternating current dynamo, D, which may be switched on to the powerful vibrator or oscillator immersed in the liquid-filled tank, buried in the ground, or mounted in the hull of a ship. Whenever the telegraph key is depressed, powerful sound waves will be set up and propagated thru the intervening medium. The sound waves are picked up by means of the same oscillator, or else by a sensitive microphone, placed in a tank containing liquid, in the same way as at the

Employ sonorous or sound wave vibrations transmitted thru the ground, and thus we know that the ground, and also water, are good sound conductors. The Indians used to hit two rocks together, one of which was partly buried in the ground, or else hit a rock with a tomahawk or hammer, and by various other means, transmission of powerful sound waves was effected. The "code" message was picked up by another Indian located some distance away, who placed his ear close to the ground. Not only this, but the Indians, not to mention the early pioneers, were experts in detecting the

mission and reception of intelligence. This system is in use on submarines and steamships as well as war vessels at the present time, and has saved many lives.

The present invention deals with a new and more sensitive method of mounting powerful electro-magnetic vibrators (or "oscillators," as their inventor calls them) in sunken pits which are filled with a liquid, such as water, oil, etc. The electric circuits for either telegraphing or telephoning by sound waves thru the earth or water, will be readily understood by referring to figures 1 and 2.

Magnetic and Other Fool War Dreams

AS TOLD BY THE "ELECTROMAGNET"—HIMSELF

YES, I am the much maligned and all-powerful "Electromagnet," bone of contention among patent liars, inspiring engineers, and heaven-inspired inventors of all ages, from twelve to a hundred and twelve. Recently I paid a visit to the Editorial Sanction of the Electrical Experimenter, and some of the inspired contributions and ideas I saw there, reposing gracefully in the waste baskets of the editorial and consulting staff, were from my more or less uniformed Over-Lords, who would have me perform some of the

tended rather for the Naval Insulting Board, address Chillingmycoat, Greenland, conveniently situated so that these precious ideas could be placed in cold storage and thus prevent their being lost to an ever waiting world.

One of the first would-be patents marked for the attention of the Naval Consulting Board was remarkable idea No. 1. This invention proposes to do nothing less than utilize my all-powerful magnetic attractive force at the ends of long booms, spaced liberally around the "dread-naught," so that of steel plates when they were bank up against me, or at most not over an inch or so away from me and lying perfectly inert, that I could not lift a fraction of a ton or even a few pounds ten feet away!

And so the merry patent war goes on—_inventors may come, and inventors may go_, but the "magnet fiend" will live on forever.

While browsing around thru other more or less startling inventions, I ran across the masterpiece—No. 2—there illustrated by the editor. The "inventor" was no low-brow or cheap-skate by any means. He proposed

when the naughty torpedoes come skipping along so joyfully thru the water, the chief electrician can throw in the main switch and feed me 110 volts and God-knows-how-many-amperes, so that I will instantaneously, according to his idea, proceed to exert an all-pervading magnetic power of presumably several thousand tons thru a radius of several hundred feet. Maybe that bird would like to know that if I had a diameter of six feet, and could lift twenty tons taking my co-ally, "High Potential," and injecting several billion kilowatts so as to boost the corona or efflux of my old friend "H. P." so that he could hurl himself thru space to any convenient distance, say several hundred miles, so as to thoroughly electrify all harboors, bays, inlets, and whatever enemy war vessels are wont to congregate, and even the ocean itself. Talk about your "Flying Dutchman." Gosh! but that's a

Why Is a "Blimp"?

By W. EDOUARD HAEUSSLER

KITE or observation balloons as they are termed, are used extensively in all of the theaters of the present war. Together with the innumerable airplanes employed by both sides, they constitute the most important means of observation and artillery fire control. Where there occurs a practical immobility of the lines for long periods of time, a case that is especially true in trench warfare, the observation balloons are particularly useful. It does not necessarily follow that these balloons cannot be used to advantage on marches. They can and are used even then, tho only under most favorable conditions.

Kite balloons are big and awkward to handle, and the manner of letting out and hauling in the balloons is interesting. The arrangement, for in case of attack or due to sudden high winds, the winch truck can travel along in the proper direction while the balloon is being hauled in. These winches are arranged with a separate engine to wind up the cable, but the drum may be operated from the auto engine when necessary, or both engines can be used for either the auto mechanism or the cable winch. The Germans are said to have used railroad locomotives in one case to haul down their observation balloons when a particularly rapid advance by the Allies threatened to envelop them, balloons and all. "Blimp" crews operate at altitudes of five thousand to six thousand feet usually, altho a twenty-five hundred to three thousand foot level is common, all depending upon the aerial activity of the enemy, and the extent of territory over which they have to observe.

Locomotives are also brought into play by the Allies in this interesting arm of the military activities, a very important branch when it is considered that the observation balloons are the eyes of the army. On a flat car there is mounted a motor-driven winch of the modern reciprocating, automatic adjustment, cable drum type, of extremely positive action. This car is trailed behind the locomotive in conjunction with an additional box car and another flat car. The box car is used to convey the gas stored under enormous pressure in steel "bottles," and the second flat car has the important service of carrying the balloon, bag and basket complete. The locomotive is of the armored type, and we therefore have a formidable "spy" in the shape of this aerial observation train and its equipment.

Beside carrying the gas on the flat cars, motor trucks or "camions" as they are now called throughout the Allied army, there are also generating stations situated behind the lines. Here the hydrogen gas is electrolytically produced on an enormous scale. The gas is generated in fairly large cement tanks that have been built into the ground, the tops of these tanks being placed flush with the level of the surrounding earth. These entire apparatus are camouflaged covers, hiding the plants from the eyes of the "boche" aviators. The cells are likewise made of cement, and are sixteen in number to a unit. The hydrogen gas is gathered by collector pipes that lead the gas to the gasometers or measuring instruments. It is then allowed to pass into the intake end of a force pump, compressed and forced out of the exhaust side, into the steel containing "gas bottles" as they are popularly termed "Over There". The oxygen that is generated simultaneously with the production of the hydrogen gas, is stored...

ELECTRICAL EXPERIMENTER

453

and used by the “Gas and Flame” Squads. The oxygen is combined with acetylene, thereby creating an intensely hot flame upon ignition.

In the construction of the balloon bag, almost without exception, the panel system of manufacturing is adopted, i.e., rectangular panels of fabric cemented and sewn together in the same form as bricks are laid. There are at least twelve of fabric in the ordinary balloon; in places there are three. This refers to the gas-holding envelope. The rudder and the interior ballonet is generally only one ply thick. Where two or three ply material is used, it is cemented on the bias, thus gaining enormously in resistance to tears. As a matter of fact, it is almost impossible to tear three-ply balloon fabric with one’s hands.

The U.S. Navy “blimps” are of the French type, measuring ninety feet long by thirty-five feet in diameter. The greatest beam, to speak naively, is about one-third of the length from the bow to the stern. From here it tapers off somewhat toward the stern, thereby gaining a streamline effect.

The “blimps” have air filled rudders which resemble a large “earth worm,” extending clear around the center belt at the back of the gas bag, and also down and under the rear section. One side or the other of this air-rudder compartment is filled or emptied as required, thus presenting more or less head resistance to the wind and causing the ‘blimp’ to swing around to the right or left as desired. The observer’s basket is slung well below the gas bag so as to ride easily, and also to enable the pilot to cut loose with his parachute, in case the balloon is hit by an incendiary bullet or shell and set on fire.

The appendages attached to the rear of the balloon, are technically known as the air-rudders. Their principle involved in the operation of this air-rudder is extremely simple; it is nevertheless rather difficult to describe in mere words. The action of the ballonet can be better understood by referring to the illustration where the observation balloon is shown in section, looking at it from the bow at the point where the automatic valve cord runs transversely across the balloon. The reader, I trust, can understand from this illustration just how the valve works.

The automatic valves, H, are connected by a cord, X, to a stop immediately opposite to itself. Riding on this cord is an aluminum thimble, C; the thimble is fastened to a series of spider-legged cords, K, with this gas. Due to the expansion and contraction of gas in direct ratio to atmospheric conditions, some means necessarily had to be adopted in order that the shape of the balloon would remain the same at all times. In other words, the internal pressure had to be maintained at a certain constant. To accomplish this, the air-filled ballonet was adopted.

The ballonet is located in the interior of the balloon proper, and it runs diagonally from the forward end to the upper surface at the rear end, or stern of the observation balloon.

The physical action of the automatic valve comes into play when the gas in the upper portion of the envelope expands. This expansion of the gas forces the upper wall of the ballonet downward, thereby keeping the internal pressure constant. As the ballonet is forced down, it takes with it the spider legs, K, which in turn draw the aluminum thimble with them. The thimble, riding downward on the automatic valve cord, X, pulls it, and the increased tension opens the valve, allowing the gas to escape.

As the gas escapes, the internal pressure tends to become less, and the pressure of the air in the balloon, which is equal to that of the wind, entering it indirectly from the air-rudder, forces the ballonet, A, upward, and as the tension is removed from the thimble, the valves, H, due to their self-contained spring loading, automatically close. The hand valve produces the same action, and the gas can be made to escape by the pilot pulling this rope at his discretion.

While the shape of the rudder will not be amiss here, and it will serve to show how the air in the balloon is put under pressure by its action. This rudder is situated on the outside of the main bag, toward the stern and underneath. It is a sausage-like arrangement running toward the stern and ending in two small pipes which are communicative with the fins. These fins approximate the shape of the rudder, and are placed toward the stern of the bag and at its ‘equator’. An aperture of about one inch in diameter is located at the forward (Continued on page 492)
NOVEL X-RAYS

AN INTERVIEW WITH THE "ED"
By "Fips", Office Boy

AFTER several sleepless nights, I finally made up my mind to interview the Chief, even tho it would cost me my job. A certain matter disturbed me and I simply had to get it off my chest. So I cautiously pussyfooted in to his sanctum, climbed on a chair, and ambushed him by way of an open transom. The prospect did not look very promising. Our Editor-in-Chief was very, very busy. With his left hindmost foot he was O.K.ing "E. E." press proofs, by means of a rubber stamp attached to his heel. He glanced at the proofs thru an inverted periscope. To his left ear was strapped a telephone receiver over which the latest electrical and scientific news came trickling in. Of these he made notes using his left hand to write them down in Morse code on a constantly moving paper tape. He was just discussing the next "E. E." cover with the cover artist, and that poor mortal was perspiring freely trying to devise some brand new color scheme that would—in the Chief's language—"knock 'em dead"!
The Chief wanted an ultra-violet-skies, tinged with a carbuncle-heliotrope shade. The war machine—which was sure to win the war this trip—and which was to form the hair-raising subject of the cover—was to be a deep Hun-blooded red-vermilion, with garlic colored reflexes, while the wheels were to be of a deep-frozen helium-argon shaded gray, with canary-colored aigrettes on the hubs. Our soldiers were to be camouflage in chameleon (changeable) colored uniforms, with lilac scented colthoppers! The dead Hun's piled sky high around the machine were to be attired in "Frankfurter"-colored lingerie, while the Hun officers were to appear in Sauerkraut-colored pajamas, with X-Ray green complexes—indicating death by concentrated Sauerkraut-gas.

"War sure is hell," muttered the poor artist as he walked unsteadily from the sanctum as if in a trance, trying to memorize all those colors. Trembling I entered the sanctum, altho I knew from experience that the Chief, having delivered himself of his monthly "atrocity", would be in a fair humor. Indeed he was. With his right hand he kept throwing rejected manuscripts into the waste-basket, while with his disengaged right foot he shaved hundreds of rejected "Phoney Patents" into a trap door in the floor. Down they went right into the automatic paper baling machine located in the cellar. The Chief, for once smiled. Why shouldn't he. Business was good—injected M.S.S. For if there was no money in the magazine bus-ness, due to preposterous paper prices—he always sold $50.00 worth of baled manuscript paper a day! And that didn't cost him one cent. Besides most contributors use good paper, too, which commands a higher price! After discreetly coughing a couple hundred times to attract his attention, I finally caught the Chief's eye.

"Well, what is it?" thun-dered he, working right ahead with his four extremities.

"Anointed Chief," I said, "there have been millions of requests recently from your worshipping readers, who are begging you on their knees to publish your august countenance."

"Withering inexact," yelled the Chief, "fool, knave, wouldst thou deprive me of mine daily bread? Yon letters mean 50 simoleons in baled paper to mine income a day, at present market prices."

"I thought of all that, Chief. But suppose I know of a way to publish your picture, and still get the letters?"

Instantly the Chief was all attention and I explained my plan to him minutely.

Next morning I walked into his sanctum with the proof of the adjoining X-Ray photo of his head, and after he had snorted his approval of it, I began:

"Illustrious Mumbo-jumbo! Your ecle-mosny servant would fain address several questions to his august master—"

"Why August?" exploded he, "this is September, is it not? But proceed and be short!"

"Chief," I began, "it is of paramount importance to your readers, just where all those classical ideas of yours originate? Do they find their birth in these white, blank spaces, of which there are so many scattered through your revered dome?"

The Chief grew pensive: "Not all of them," he said, "only strictly ethereal ones."

"What accounts for the extraordinary emptiness of the upper, back section of your skull, Chief?" I continued.

"Very simply explained. At the time the exposure was taken, I thought of you. Naturally my mind was blank!"

Electricity Aids Hun "Movie" Spies

By GEORGE HOLMES

AGAIN we have the unfailing "Movie" to supply the thrill which all must experience to get away from the humdrum of every day life. This time our reportorial eye was glued to see the "writing on the wall," as it were, and with a little sleuthing on our part we

Lertz gives him money to carry out the plot.
Dr. Wolf prepares germ cultures and from it a paste impregnated with the living germs. Thru this paste he permits common house flies to walk, thus transferring the germs to them. Then the flies are re-

This instrument gained the first information which the Secret Service received in regard to the plan of the Imperial German Government's spies and plots in America to destroy the Du Pont de Nemours munitions plant at Hopewell, Va. A woman suspected of being in sympathy and in the con-

came back with some more scenes from that truly dramatic photo-play masterpiece—"The Eagle's Eye"—which is doing much to show our stay-at-homes what the vigilance of the eternal Secret Service has protected us against.

First is the plot to spread the dread epidemic of infantile paralysis throughout the land. Dr. Wolf is a chemist, German born and trained, who has a small laboratory in a tenement section of New York. (See Fig. 1.) In a medical journal he learns that it is possible to isolate the poliomyelitis germ, the cause of infantile paralysis. A scheme for causing an epidemic occurs to him. He goes to Heinric von Lertz and explains that the number of deaths which will result will so weaken the morale of Americans, that the possibility of the United States joining in the war against Imperial Germany would be removed forever. Von

leased to scatter the germs to the food of the city.
He next begins drinking, in an excess of enthusiasm over the success of his plot. He falls, in a drunken condition on the table of his laboratory, cutting his hand on a broken culture tube. He is infected with the dread disease he has caused in so many helpless children, and dies in agony.

Petty jealousies on the part of women have caused some of the greatest catastrophes of history. Yet this trait on the part of the eternal feminine has often been turned to good advantage, and in one instance it was the direct cause of the Secret Service gaining the first information of one of the most gigantic plots planned by the Imperial German Government's spies and plotters in America. In this case resort was made to the use of a dictograph to listen in on the conversation of the plotters.

The suspicion of Ambassador von Bernstorff, Captains Boy-ed and von Papen, and Dr. Heinrich Albert, the four leaders of the Kaiser's spy army in America was shadowed to a hotel. The operative who had followed them had no trouble in obtaining the room next to the one assigned to the suspect. The microphone was then attached to the door between the two rooms and the operative affixed the head-phones. (See Fig. 2.) Information was not long in coming. The suspect had a caller, also a woman. A quarrel ensued in which the suspect accused the other woman of attempting to usurp her place in the confidence of the Imperial German spy leaders in America. The quarrel exposed the fact that the accusation was based upon some plot suggested by the caller in regard to the munitions plant at Hopewell.

Electrified Barriers Stop Fish in Streams

On many occasions, particularly where large irrigating ditches are in use, and also in many large fisheries where fish are hatched and often are guided through different water channels from one lake to another, composed of heavy iron or other metallic wire, which may extend nearly to the bed of the stream or ditch. The different strength currents are applied, as the illustration clearly shows, to the successive barriers, so that the weakest current of all sizes at such places will be turned back without fear of killing the smaller fish, by subjecting them to a sudden charge of excessively heavy current, which might easily be the case if but one electrode charged at a fairly high potential were employed. As will be seen, one side of each of the transformer secondary coils is connected to a common conductor which is grounded, i.e., connected to earth. Thus, the current will pass thru the earth, thence thru the water to the respective metal wire barriers hanging in the stream. The metal wire barriers or rods do not need to be very close together, and yet they will protect as efficiently as a small mesh net.

According to a French electrician, the temperature of the carbon filament in an incandescent lamp approached 2,000 degrees.

These Spectacles Carry Their Own Light.

By Frank C. Perkins

The accompanying illustration shows an electric spectacle lamp and frame developed by an Idaho inventor, Mr. Ladislaus Zacharia. This electric spectacle lamp and frame provides means of bringing powerful electric lighting on a spectacle lamp and frame around the eye or eyes in the forehead, in order to exclude shadow from the side of the object where it is desired to see it clearly and yet leave both hands of the user free. It has an electric wiring system inside of the spectacle frame. For instance, a hollow socket and a passage thru the center of the lamps may be provided and a dark sleeve inside the passage of the lamp will enable the user to see the object clearer.

There is provided a cylindrical passage in the lamp which curves out on the point of the lamp and this curving can be shaped to any desired design. It is intended to give the eyes protection from overstraining by virtue of limiting the view thru openings in which dark tubings are mounted, thus protecting the eyes from too powerful light rays, the wide protecting frame catching the rays and throwing them back from the direction of the face. The bulb can be equipped with small reflectors if desired.

The Mystic Trio—Who are they? Ah! The secret is out, they are wearing the very latest in "spectacles." Each pair of glasses carries its own electric light between the lenses, current being supplied from a small pocket battery.
How Can We Tell “Real” Death?

By H. WINFIELD SECOR

CONSIDERABLE research in the realm of that branch of medical science dealing with real and apparent death shows that medical men practically agree that in view of the facts available on the matter, and also in view of their various experiences, that it is possible to determine to apparently die, and yet be in such a perfect trance or state of syncope that they can deny practically every ordinary test which the physician might apply, to determine if life had entirely left the body. Briefly, the facts in a number of such cases show that the respiration or breathing function may drop to such a low point that it is imperceptible and will not show on any ordinary indicating apparatus, as for instance the well-known mirror test. Also the person may be in a trance state with the heart functioning at such a low state of activity that it is impossible by any ordinary means employed by the physician, to determine whether the person is actually dead for all time or only in a temporary trance. These facts are of vital importance to all of us and of supreme interest to be sure, for we have all heard or read of persons being buried alive or while in a trance state.

Many people probably have scoffed at such statements or stories, but there are a sufficient number of cases on record to prove the point we are making. We know all concerning human life, and as to what the real germ of life is. For instance, if one will go down to the New York Academy of Medicine, and there consult the records of a number of eminent British physicians and scientists who visited India some years ago, they will find the official records of many of which are sworn to, covering the wonderful performances of the so-called Hindu fakirs. These exponents of advanced science can place themselves in a state of suspended animation, or syncope, for long periods; even for two hours, but this is not true. The patient, however, did present a remarkable case, and a short syncope did occur. Dr. Overton recalled two cases in his experience where a syncope, or state of "suspended animation," occurred for a period of about five minutes. The patients were pronounced dead to all intents and purposes, after all tests, including those of respiration and heart action had been thoroughly carried out. A very remarkable and little known experiment was carried out in these two cases, that of injecting adrenalin into the heart proper with a long needle syringe, a quantity of the substance sufficient to cause death, as indicated by the heart rate of the stethoscope being sufficient. These patients were brought back to life in this way (these experiments having been conducted at a well-known New York hospital) after all bodily processes and organic functions had ceased, in a period of suspended animation lasting about five minutes. One of these patients, a woman, was successfully resuscitated in this way and died eventually of contracting pneumonia. As Dr. Overton explained, "We cannot boost the heart or cause it to work beyond its limit, once the critical period in its life has been reached." But in this case the patient was an alcoholic and had been under severe exposure to the cold when received at the hospital. The second case was that of a man, and at last account he was still alive. The writer knows of a case where a woman thirty years of age passed into a state of suspended animation, due undoubtedly to a severe sickness thru which she had passed and who resuscitated herself after a syncope of twenty-four hours; this lady is alive and well today at the age of sixty-five years. The patient in this case had been pronounced dead by the attending physician, and came back to a regular state of life and activity when in her coffin. Hence when all is said and done, we are vitally interested beyond the peradventure of a doubt.

... in knowing what medical science has found out today in order to determine surely and accurately when life has past from the body, and below are given the principal tests which are used, as well as a number of newly suggested tests for this all important determination. Before proceeding further, it is well to remember that all undertakers today embalm the body, and the embalming fluid, (Continued on page 498)
Searchlights With Aircraft Sound Detectors

The accompanying photograph shows one of the large Austrian searchlights used on the Italian Front in the recent offensive by that country. As will be noted this search-light is equipped with special sound detectors comprising a series of large megaphones mounted in circular fashion about the searchlight frame, so that when the operators quickly move the searchlight and adjust the mechanism, an approaching aeroplane, or fleet of enemy aeroplanes, will produce the maximum sound in the acoustic receivers attached to the megaphones. Thus the searchlight beam will automatically and simultaneously be focussed in the same direction to that in which the megaphones are pointing.

This unique arrangement for locating and revealing the enemy aircraft is used most efficaciously and effectively. It is quite surprising to learn that a simple megaphone of even small size, such as that here shown, will indicate the approach of an aeroplane, owing to the great volume of sound given off by the gasoline motor propelling the plane. The French Aerial Observation Corps have made very extensive use of these megaphone aircraft detectors. They have been much employed in the larger cities of France, including Paris, for detecting the approach of hostile aeroplane squadrons or even a single enemy plane, even when they are several miles away.

The object of using these megaphone horns is that they will respond with the maximum sound when they are pointed to within even a few degrees of the source from which the sound is emanating, which is in this case, of course, the enemy aeroplane motor. The photograph, as aforementioned, shows Austrian observers listening for the approach of Italian aircraft. With such devices available it is possible for the military intelligence department to ascertain the approach of enemy bombing planes when they are at a considerable distance, and when thus armed with this advance information, it is a simple matter to bring up the anti-aircraft artillery, many of the guns of which are mounted on high-powered automobile chassis, and provide a very warm reception for the enemy intruder when they arrive on the proposed scene of action.

HEAT AND LIGHT TREATMENT LAMP

The illustration shows a new and improved thermo light, which has been designed along scientific lines for the proper infusion of electric light and heat. This unique reflector so directs the heat rays of the special lamp that they produce the best results with minimum current consumption and without the rapid deterioration of the filament.

The heat rays are effective over an area of approximately 50 square inches and not focussed in a small burning spot.

The outside shell and inside reflector are constructed of aluminum, making the device very light in weight, which permits prolonged treatment without fatigue.

It comes complete with lamp, to operate on any direct or alternating circuit not exceeding 125 volts, 3 feet cable and attachment plug.

A group of European electricians decided, after experimenting, that better results were obtained by placing the carbons in arc lamps horizontally and one slightly above the other, suitable gearing, so as to cause the two sets of wooden or other rollers to travel on endless chains. By means of the two handles shown on the right and left hand sides of the machine, the two uprights carrying the moving roller belts, can be moved toward or away from the "patient's" body, until they are adjusted accurately for each particular case. Also the upper rollers carrying the drums over which the roller belts travel, are adjustable and can be moved up and down vertically, so as to permit the belts of the top rollers to conform accurately to the shape of the body.
New Westinghouse Research Laboratory

The research work of the great Westinghouse electrical concern has always been carried on under the direction of the engineering department. In 1900, the research division was organized as one of the several divisions of the engineering department, and it now has under its control seven laboratories.

The work of the division includes activities which are not usually class as research work in other organizations. For example, it has charge of the preparation of all specifications for the purchase of the materials used by the company, together with the experimental and development work leading up to the writing of these specifications, says Mr. C. E. Skinner, the chief engineer and Mr. R. W. E. Moore, in a recent article describing these interesting laboratories. Mr. Skinner's photo is reproduced herewith. First there is a process section, which has technical control of all the various processes used by the company in the manufacture of its product. It has charge of the routine chemical and physical testing for all departments, including the inspection departments. It has technical control of the various metallurgical processes, such as those involved in the brass foundry.

Fair Telephone Operators Join Uncle Sam Overseas

HURRAH for the fourth unit of telephone operators, already taking its place in France beside the other three, and making things hum "over there!" The cable "Arrived safely," is brief, to be sure, but what it really means to say is, "Sixty more French-speaking American girls have arrived in France to operate war switchboards for Uncle Sam and our boys." They have volunteered to do this as their contribution toward winning the war, because they feel that it is the thing that they can do best. As one of them put it, if they didn't go they would feel like slackers, and would be slackers just as much as any man who shirked his duty. More are ready to go, but they are not needed at present, and are continuing their training over here.

With minds filled with the end to be attained, these girls and those who preceded them, together with those who are to follow, have traveled from the four corners of the United States.
A Gyro Electric “Movie” Camera for the Battlefield

PHOTOGRAPHY fills a most important niche in this business of Kanning the Kaiser! There is hardly a branch of the service that is lacking a camera- man, whose business it is to bring back an indestructible, true, and vivid record of what is going on “Over There” in the fight for democracy. And thus will our children’s children be able to see the struggle that was made to preserve the liberty of the good old U. S. A.

The strides made in the art of recent years reflect what an advance has been made over the now seemingly antique methods of photography used in the Civil War.

In the days of ’61 no great interest was evinced in the hazardous task of taking pictures under battle-front conditions and on the march. The very few men interested enough to undertake the task were mostly “free lances,” doing things on their own hook. Considering everything we are to-day indeed fortunate in still having a number of these photographs, whose value shall increase in the years to come of that memorable struggle between the North and South.

All this is now changed. On every battle-front you will find the photographer. Whether on land, up in the air or on the sea, you will find him turning his crank or clicking his Graflex.

To overcome some of the difficulties experienced with the standard movie camera one large camera concern has devised a new type of machine adapted for use under the most adverse conditions.

It is constructed on much the same lines as the usual motion-picture camera, but more substantially, so that it will outlast the wear and tear of service on the battle-field. The film magazines, shutter, take-up arrangement, lenses, etc., are located on one side of the camera and identical with the usual machine.

On the opposite side may be seen the electrical drive for the film. See cut above. The motor is self-contained and fitted with ball-bearings to ride the friction and make the driving almost noiseless. The motor is geared up so that at its maximum speed the machine takes about 24 pictures per second; its speed of the motor as well as the starting is controlled by a small lever on the side of the case which, when pressed, causes resistance to be put out of the circuit and the motor gains speed. Two dials are set in the top of the camera to show the speed of the film.

The all important feature is the small stabilizing gyroscope placed on the front end of the camera and driven by a separate electric motor. After the gyroscope has attained its maximum speed of 5,000 r.p.m. (it takes about five minutes to do this) it becomes possible for the photographer to move about, run, walk, ride and do numerous other things, while he simply holds the camera by the two handles (on each side). The camera will always maintain its horizontal plane and take distinct and clear pictures, without resort to a tripod or similar steadying device which would otherwise be necessary and always in the way.

The battery is set in a separate cabinet and consists of a set of twelve storage cells, the casings of which are made of light celluloid and fast into one solid unit. It delivers a maximum of twenty-four volts and about ten amperes.

The cells are so arranged that the acid cannot spill should the battery be overturned or upset.

The Latest Gyroscopic Electric “Movie” Camera for Use in Photographing Battlefield and Aerial Views. The Gyroscope Holds the Camera Steady at All Times.

Extremely Compact Electric “Movie” Projector for War Camp Work. Y. M. C. A. “Huts,” etc. etc.

Next after taking our pictures and developing and printing them comes the need of seeing what we have taken. The regulation (Continued on page 504.)

IMPROVED LOUD-SPEAKING TELEPHONES.

The loud-speaking telephone has come to stay—only a few years ago it was practically unknown outside the laboratory. It finds manifold applications daily and you are apt to meet it most anywhere nowadays.

A new type of duplex voice-transmitter is illustrated here. It is a very sturdy instrument manufactured for severe usage.

On quite a few installations of this apparatus as many as a thousand calls are made in twenty-four hours, day after day.

Generally it is the telephone operator who uses this equipment. A telephone operator is always in a hurry and a transmitter designed for the operator to take up and lay down every time she uses it, does not stand up as well as a transmitter mounted on an extension telephone arm, one type of which is here shown. This improved type of transmitter is made without any movable joints and in as few pieces as possible.

The reproducer horns are located in the walls in flush type containing cabinets when possible, as this makes an unobtrusive installation.

Since the reproducer horns are up out of the way where they are not subjected to wear, and because they have no moving parts to wear out, their life is practically unlimited.

The reproducer itself is mounted in a dust-proof case, and is fully protected against rusting.

Ordinarily there is but one switch used on these loud-talking systems and that is used for turning the current on and off. Standard switches are used.

The latest type of reproducer has as nearly permanent adjustment as possible. The reproducers are “seasoned” before shipment, so as to take care of any settling of parts.

The duplex voice-transmitter is designed for use on installations of from ten to twenty loud-speaking reproducer horns. It is approximately twice as powerful as the single-voice transmitter, because each transmitter energizes its own individual circuit of reproducer horns. Approximately half of the reproducer horns being energized by each transmitter, there is no electrical connection between these transmitters, except that they are energized by the same current supply.

The concealed type horn and cabinet shown has been designed particularly for use in hospitals. The horn is white enameled and the cabinet is given a final coat of paint after being mounted in place, of the same color used on the walls. The hinged door gives ready access to the interior when it is desired to clean or dust inside.

Loud-speaking 'Phone Cabinet of the Flush Wall Type. Sound Emerges Thru Grill at Base. Duplex Voice Transmitter for Loud-speaker at Left.
Electric Trucks Aid War Work

Along with the great increase in woman labor in "the army behind the army," much has come the use of a number of devices which make possible a much wider application of this labor than was originally thought of. Today women are making practically all of the great quantity of munitions that is being used by the British army.

One of the pictures herewith shows women workers loading shells on one of the trains of miniature railway cars, used for moving these shells about in one of the great British munition plants. Electricity is used wherever possible to expedite handling and delivery. Overhead cranes lift and carry the heavy shells and place them at their designated places in the shell warehouses. Women operators work the overhead cranes, direct the loading of the shells on the cars, as shown by the picture, and also drive the little storage battery tractor which transports these cars from building to building. It will be seen from the photograph that the girl in the foreground, driving the storage battery tractor, is quite youthful for the responsibility of this job. However, these tractors have been so simplified and safeguarded that their operation now can be performed by practically any person.

It is interesting to note that whereas the cars of the railroad trains run on tracks, the tractor which pushes these cars about does not do so. It can haul a string of cars in and then run past this string of cars, along the aisle, and do work elsewhere while this first string is being loaded. One of the desirable features of this storage battery tractor is that there is no overhead trolley and that all danger by reason of electric arcing, etc., is eliminated.

As our participation in the war assumes greater and greater proportions we may expect to see large numbers of these little tractors in use in our own munition plants.

The other photo shows how the electric storage-battery equipped truck is "doing its bit" in our own country. During the present congested and shortage of locomotives and electrical perfection of the storage battery, insure that money-making result—most days in service per year.

Plan to combine electric plants.

Combination of electric generating systems and eliminating of hundreds of isolated and uneconomical plants is under consideration by the Fuel Administration as a means of saving fuel supplies. Representatives of the Fuel Administration left New York recently to attend hearings before the Public Service Commission at Washington, D.C., at which the subject will be taken up as affecting New York City.

Millions of tons of coal would be saved, officials say, by centralization. The plan, too, if executed, they say, would go far toward relieving terminal congestion and lightening the loads carried by rail and barge lines.

The coal administration is conducting a general investigation to determine how centralization best could be accomplished without working undue hardships on the owners of plants which might be closed.

"It already has been demonstrated," said a recent Fuel Administration order, "that in many localities centralization may be effected without hardship and with a considerable saving. England and France long ago have taken steps in this general direction. In fact, a commission appointed in England to investigate the subject has described centralization as an economic necessity. It is estimated in this report that an economic saving of $600,000,000 would be effected and the fuel requirements of the industries now supplied with electrical power cut in half."

An Electric Truck "Doing Its Bit" Somewhere in New Jersey. This Truck Equipped with Edison Storage Batteries, is Hauling Three Tank Cars Without a Whimper.
The mystery of the spiral nebulae is still unsolved. These peculiar structures exist in the heavens by hundreds of thousands. They range in size from The Great Andromeda Nebula, which covers a space about one and one-half degrees in length by half a degree in width and is faintly visible without the aid of a telescope, down to the tiny flecks of light that are invisible to the human eye directly but appear on the photographic plates attached to our most powerful telescopes after an exposure of several hours duration.

Counts have been made of the number of spiral nebulae upon photographic plates within selected areas evenly distributed over the sky with a view to determining the probable number of these objects within the reach of great telescopes. It has been estimated as a result of these counts that there are at least seven hundred thousand small spirals photographically in reach of the largest reflectors, while the total number may easily exceed one million.

In some regions these spirals are crowded together in the greatest profusion. In a most wonderful region in the constellation Coma Berenices three hundred and four faint spiral nebulae have been counted upon a single photographic plate covering an area of about three-fourths of a square degree, the a region of equal size only a few degrees distant contains but two spirals. Aside from a marked avoidance of the plane of the Galaxy and a noticeable clustering near the north pole of this plane and to a somewhat less degree near its south pole the distribution of the spirals is quite general throughout the heavens.

The reason that spiral nebulae should lie within the neighborhood of the Milky Way, which is the region favored by the gaseous nebulae, the planetary nebulae, and the vast majority of the stars is not yet satisfactorily explained. The fact is most significant and must be considered in all theories dealing with the origin and nature of the spiral nebulae. The very fact that the spirals avoid the Milky Way shows that they are in some way affected by it.

A second most marked characteristic of the spiral nebulae is their extremely high velocity of motion thru space, the greatest for any class of celestial objects. Twenty miles per second. A few stars spoken of as "runaway stars" have a velocity of one hundred or two hundred miles per second, but these are quite exceptional and they are sometimes referred to as visitors to our galactic regions from regions beyond. In fact celestial objects other than the spiral nebulae that have unusually high velocities of motion thru space such as the globular star clusters and a few isolated types of stars show the same avoidance of the plane of the Milky Way that is shown by the spiral nebulae. According to one explanation this is due to the fact that a strong gravitational field exists in this plane with its hosts of star clouds, and its vast tracts of nebulous matter, both luminous and non-luminous. Globular star clusters or spiral nebulae entering this field would not be able to remain intact but would be disrupted and scattered.

The spiral nebulae do not possess the "bright-line" spectrum characteristic of the strictly gaseous irregular and planetary nebulae that are found in the vicinity of the Milky Way but have the continuous type of spectrum such as comes from our own sun and such as would emanate from star-like bodies. The spiral nebulae are for this reason not considered to be strictly gaseous objects but a conglomeration of stars and nebulous matter. Dark streaks visible in a number of spirals that lie edgewise to the earth seem to show that these nebulae are surrounded by some dark gaseous matter.

No. 3.—The Spiral Nebula in Centaurus (N. Q. C. 5236) Photographed With the 40-inch Reflector of the Lowell Observatory By C. D. Lampland. View of a Spiral Nebula Lying Across the Line of Sight.

No. 4.—The Whirlpool Nebula (N. Q. C. 5184) in Canes Venatici. One of the Most Beautiful of the Spiral Nebulae. Its Spiral Structure Was First Detected By Lord Rosse in 1845. Photographed With the 40-inch Reflector of the Lowell Observatory By C. D. Lampland. This Nebula Also Lies At Right Angles to the Line of Sight and Therefore the Spiral Formation Is Very Noticeable.
that absorbs the light from the inner portions.

Believers in the island universe theory of the spiral nebulae consider that our stellar system is also a spiral nebula and that its form is essentially that depicted in the accompanying photographs of characteristic spiral nebulae. The spiral arms are represented in our system by the star clouds of the Milky Way. The well-known star streaming tendencies of the stars represent motions in and out along those spiral arms toward and away from the nucleus of the spiral. According to this theory dark nebulous matter may exist in outlying portions of the Milky Way similar to the nebulous matter producing the dark streaks in the accompanying photographs (Nos. 1 and 2). Such nebulous matter would hide from our view spiral nebulae lying in the neighborhood of the galactic plane and this would explain why the spirals apparently avoid the plane of the Milky Way. It has long been known that the vast majority of all the stars and the great irregular gaseous nebulae constituting what is known as our "stellar system," crowd toward one plane, that of the Milky Way; for all we know to the contrary all these stars and nebulae may form one vast spiral structure. The distance of the spiral nebulae is now known to be very great. At a distance of several hundred thousand light-years our whole system of hundreds of millions of stars would fade away into a small blurred speck in which no individual stars except the giants of the system would be distinguishable and we would appear as a faint spiral nebula appear to us. So reason those who believe that the spiral nebulae are external universes separated from our Galaxy by distances so great that a ray of light travelling with the velocity of 186,000 miles per second would take not tens of thousands but hundreds of thousands of years to span the abyss.

Until a year or so ago there appeared to be no way of arriving at a reliable estimate of the average distance of the spiral nebulae. Up to July, 1917, thirty two Novae or Temporary stars had been discovered. Of this number thirty were in the Milky Way, two were in spiral nebulae. No particular attention had been paid to the two exceptions. In July, however, Ritchey, at Mt. Wilson, found a faint star in a spiral nebula that had not appeared on earlier photographic plates. Now one or possibly two Novae might chance to be in line with spirals but hardly three. The discovery started astronomers examining past photographs of spiral nebulae for Novae with the result that eight additional Novae were found to be connected with spiral nebulae.

The facts were then that all known Novae to date had appeared either in the Milky Way or in spiral nebulae. The appearance of Novae in the Milky Way is usually explained as due to the encounter of a star with nebulous matter. The Novae of the Galaxy are suns suddenly raised to abnormal brightness thru the friction arising from the encounter of star with nebula. How then should the newly noted Novae in spirals be explained since the spiral nebulae conspicuously avoid the neighborhood of the Milky Way? It was a point in favor of the island universe theory, for if the spirals are similar in structure to the Milky Way and are great aggregations of stars and vast gaseous nebulae the appearance of Novae in spirals is not so strange. This theory was further borne out by the fact that the Novae of the Milky Way average eight magnitudes or nearly sixteen hundred times brighter than the Novae appearing in spirals. Since the apparent brightness of stars of equal magnitude varies as the squares of their distances the Novae in spirals must be on the average forty times more distant than the Novae of the Milky Way, which are members of our own system of stars. We do not know the distance of the Novae of the Milky Way, but if we assume they are at an average distance of five thousand light years the average distance of the spiral nebulae comes out two hundred thousand light years.

There is another class of celestial objects, the globular star clusters, that are now known to be at distances ranging from twenty thousand to more than two hundred thousand light years from the earth. Each
POWERSFUL LIGHT RELIEVES PAIN.

It is rapidly becoming the practise, both in private and professional circles, to apply the rays of a powerful electric lamp to various affected parts of the body. They will conquer and banish pain and other symptoms of most diseases, thereby giving Nature a better opportunity to overcome the underlying condition and lessen the amount of medicine required, it is said.

For instance, they will overcome the pain of wounded or strained muscles or pressure upon nerves, and help poor circulation, numbness and stiffness of any part following cold or injury. Nothing penetrates, heals and soothes sore areas and so promptly re-establishes the vim and vigor of the patient as the timely application of heat and light therapy.

When applied early after a bruise, as of the eye or face, they prevent swelling and discoloration of the skin. The light here shown is claimed to decrease the pain of a carbuncle, boil or abscess. In the early stages it may prevent the formation of pus; in the later stages it helps to ripen the abscess. The illustration shows a 400 candle-power cornucopia shape lamp, which consists of an aluminum hood, globe, handle, seven feet of cord, plug and adjusting ball for raising and lowering lamp over patient. There are also available colored, adjustable reflectors, ruby amber and green screens.

230,000,000 K.W. WATER PER YEAR AVAILABLE, SAYS STEINMETZ.

Dr. Steinmetz, in a recent paper presented before the American Institute of Electrical Engineers, warned his hearers, that water power can never be expected to do anything more than supplement the use of coal. He estimated the possible hydraulic energy of all American water courses as 230,000,000 kilowatts a year, a little more than the total energy now produced in the United States, thru the medium of coal. “This means,” he said, “that the theory by which we hope to use the water power of the country when coal begins to fail as an endless supply of energy is now a dream and must remain a dream. If all the potential powers of the land were now developed, and every raindrop used, it would not supply our present demand for energy.

ANNOUNCEMENT

With this issue the price of the ELECTRICAL EXPERIMENTER advances to 20 cents a copy. We have delayed this move as long as we dared, but economical conditions made the change necessary if the publication was to survive. We are forced to pay 10½ cents a pound for text paper now—an increase of 11½% SING. 1916. Our cover paper now costs 11 cents a pound—AN INCREASE OF 91%. Printing, art work, engravings—all have advanced 50% to 90% and the end is not yet. Take only one item—the two carloads of paper that go into making a single edition of this EXPerimenter, they now cost us $2,200.00 MORE than a year ago. The paper alone in a single copy of the EXPERimenter costs 55 cents! Advancing the price of a publication never benefits a publisher. He loses a certain percentage of circulation, and his subscriptions fall off. New readers at the higher price are hard to find. We therefore can but hope that our old readers will bear with us, and support their EXPERimenter until such time when we return from a war, to a peace condition, and its accompanying recession of prices. In return for the higher price, we have already added a certain number of pages to this issue, and will continue to do so if we have the full support of our readers.

It is our belief that we offer more actual instruction and information than any kindred publication, and having the confidence of our readers we trust that they will support us as enthusiastically. Uniting times of stress, as they have during normal times, Subscription from 1 up to 5 years at the old rate of $1.50 (foreign $2.00) will be accepted up to and October 31st inclusive. After that date the new rate of $2.00 a year, ($2.50 foreign) will be in effect.

THE PUBLISHERS

A PORTABLE NITROGEN RADIATOR.

The latest offering to the public is the portable electric nitrogen radiator shown in the accompanying illustration. This radiator is said to be the only auxiliary electric heating apparatus filled with nitrogen gas which is built on scientific principles adopted by heating engineers of standing—i.e., the radiator.

It maintains an average temperature of 350 deg. Fahr. (176.7 deg. C.), it is said. The radiator contains an electric heating element surrounded by nitrogen gas. The gas fills the entire inside of the radiator, which is hermetically sealed. The gas serves to carry the heat from the heating element to the radiating surfaces at a temperature higher than that of a steam radiator. One feature pointed out for this device is that there is no way by which clothing, drapery or anything else can catch fire, as it has no exposed red-hot open wires. The cost of operation of this radiator is very low. The stock radiators are made in four, six, eight and ten sections.

STAND BACK! HERE COME THE ELECTRIC TANKS!

The very latest addition to toyland is the miniature electric tank here shown. The tank is a miniature model of the famous British Tanks which are playing such an important part in the Great World War at the present time, and it works to perfection. There is no end to the fun boys can have with this small war model and it will climb over anything that is in its path. No matter what is in front, it keeps right on forcing its way ahead.

The tank is driven by a powerful battery motor and can be supplied with current from battery developing 8 volts, or thru an A. C. step-down transformer on 12 volts.

The Electric Tanks Threaten to Invade Toyland in New York and all Other U. S. Cities and Towns on Xmas.
The Gyro Electric Destroyer

By H. Gernsback

We reprint below a few paragraphs relative to the Gyro Electric Destroyer, originally described by the author in the February 1918 issue of the Electrical Experimenter. This article was widely reprinted all over the country, from the New York World to the San Francisco Chronicle. We re-publish part of the article for the benefit of those readers who did not see the original.

The great trouble with the Tank is quite a sensitive trait. If hit, even the bullet of a small gun will generally cripple the Tank. The tank is the most vital part of the machine, and if damaged in one spot, it will be helpless to move or to attack. The weight of the tank is very enormous, and this makes it quite a good deal of trouble.

Attention is called to the fact that the movable belt tread of the Tank is quite a sensitive trait. If hit, the bullet of a small gun will generally cripple the Tank. The tank is the most vital part of the machine, and if damaged in one spot, it will be helpless to move or to attack. The weight of the tank is very enormous, and this makes it quite a good deal of trouble.

The present gyro electric destroyer is a single steel wheel, as clearly shown in our accompanying illustration. It is 10 feet high. The top of the wheel is not flat, but is in the shape of an arch. The weight is somewhat lighter, and it is nearly as much as the weight of the tank. The wheel itself looks like a huge ferris wheel, and is constructed of channel steel steal; in order to make it as light as possible, it has no continuous track around it, but rather the steel pieces at the circumference are spaced about one foot apart, leaving room for two inches. The weight is cut down. Second, much better purchase is had on the ground, the machine not being apt to slip as was the case of the Tank. If the top of the wheel was solid.

The wheel has one large shaft passing thru the center and extending at each side, as shown in the cross-section in our illustration. This shaft is hollow and need not weigh very much. It is constructed of very heavy steel bolts and at the ends of the shaft the latter is provided with armored projection. So as not to be damaged in case of shell fire. In the center of the wheel is suspended the engine car which comprises a gasoline engine of some fifteen hundred to five hundred horsepower. The energy is fed to a generator as shown. The result of the strange manner of using the engine is that it may be used for purposes of the wheel only; they are attached by means of a choral shaft shown.

Inasmuch as the wheel of the destroyer is not solid but contains steel, it may very well be understood that even a large size wheel will easily pass thru the machine without doing much damage, and here is where this machine shows its superiority over the tank. It will be almost impossible to damage this destroyer by means of shell shot. Even a "dead hit" from a medium caliber gun will cause much damage, and even a good sized shot hitting the gyroscopic will not hurt it very much, for the reason that the latter spins at enormous speed, which will certainly deflect the shot unless, of course, if it is a dead hit at right angles to the face of the wheel. The external drive shafts are encased and protected, and it should be as safe as possible to prevent the machine being done out of action, and this can be readily done in case of need. Another point is that this machine, the most vital part of the machine, presents but little surface to an opposing shell, contrast thereto you will have to make a large and very large moving pieces, then send along your contribution, using the accompanying blank. You might read the letter from the people who believe in the idea, reprinted herewith:

**EVERY LITTLE HELPS.**

"I sure would like to give more, as I think it will work out all right."

-- Hays, Kans.

**CALL AGAIN!**

"Enclosed find Money Order for $1.00 to go as part payment in the Gyro Electric Destroyer. I am sorry that I cannot at the present time give more, but if not enough is raised to build a fair sized model please call again."

I am very glad you gave me the opportunity to do, something of this sort before I am drafted, which I soon will be. When this Destroyer is completed, I should like to have a part in the crew when it is completed. May I suggest that you submit the plans to Henry Ford. I would not be surprised if he could be induced to build it; this would save a lot of money for the Government."

"I was not in the 'E. E.' and so did not see the Destroyer in the February issue, but am going to buy them from now on until the Destroyer is finished."

-- Walter Holey, Norwich, N. Y.

**I HEARTILY BELIEVE IN THIS MONSTER.**

"I heartily believe in this monster, and I hope that your experiment succeeds and that every reader of the 'E. E.' contributes as much as possible. I do not mean the 'E. E.' and so did not see the Destroyer in the February issue, but am going to buy them from now on until the Destroyer is finished."

-- Fred Van Dyke, 52, Gibson Ave., Detroit, Mich.

**HE SAW THE 'POW-WOW'!**

"I saw the 'pow-wow' in the 'E. E.' and agree with you. While it never occurred to me, I am contributing to the construction of that Gyro Electric Destroyer, now that it has been proposed. Enclosed you will find $1.00. Since you have it up, get your battle-scarred brain to work and make it possible. Here's hoping that you will have the best of luck and the 'Bugs' all cooperate with you."

-- Neil W. Beeson, 9 S. 3rd St., Marshalltown, Ia.

**A GENUINE BELIEVER.**

"Please see my letter of August 19, in which I enclosed $1.00 as my share in building a model of our Gyro Electric Destroyer. In that letter I mentioned the..."
A ion is a pretty small particle of matter to be made visible. It may consist of several electrically charged molecules grouped together, a thousand times too small to be visible in the strongest microscope, or it may be an electron or free atom of electricity which would be more than one thousand times smaller still. As has been previously stated these almost infinitely small particles can never be seen by the human eye which has such a limited range of vision. However, they may never be directly visible but they have already been made indirectly visible by the experiments of C. T. R. Wilson. These experiments not only are very striking in their nature but they have told us things about electricity and matter which we could have known in no other way. Electrons, and alpha and beta rays from radium may pass directly through ordinary molecules, and molecules themselves are not solid discrete particles as they were once thought to be, but are in every case points of electric energy far, far apart in relation to their size.

C. T. R. Wilson in 1912 made ions visible indirectly by photographing their path in the following remarkable manner: The principle made use of was the fact that an ion of high velocity forms other ions by collision with the ordinary molecules in its path, as mentioned in a previous article by the author. So he used a chamber of the form shown in Fig. 1, in which an expansion of the air could be obtained thru the opening P, connected with a pump. The space above the water W was first cleared of ions by an Electric Field; then an Alpha or Beta Particle was allowed to pass thru the Chamber in the direction A-A. The Air was Expanded and the Water Vapor thus formed, at Once Condensed about the ions. Fig. 2 represents the paths of alpha particles as photographed in the manner explained above. Fig. 3 represents the paths of beta particles and Fig. 4 represents the paths of X-rays. It will be noticed that these paths are strikingly different. The alpha particle travels in a straight line and the ions produced by it are so close together that it makes the line look continuous. The beta particle travels in a fairly straight line but it produces fewer

**LAST CALL**

On November 1st the subscription price of the "Electrical Experimenter" advances to $2.00 (U. S. Canada and Foreign, $2.50). This is the last chance to subscribe at the old rates ($1.50 in U. S., Canada and Foreign $2.00). No subscription for more than five years at the old rate accepted.—THE PUBLISHERS

This Chart Shows the Paths of "Beta Particles"—After Photograph by Wilson. Note the Difference Between Path Routes of Alpha Particles Depicted in Fig. 2. The Alpha Particles Travel in Nearly Straight Lines, whereas the Beta Particles Travel in Curved Paths. The Alpha Particles May Travel 7 Centimeters in Air. The Paths Taken by "Alpha Particles" in Air—After Photograph Taken by Wilson with the Arrangement Described and Illustrated at Fig. 3. Alpha Particles May Travel 12 Centimeters Thru Air. The Paths Taken by "Alpha Particles" in Water. After Photograph Taken by Wilson. The Alpha Particles Travel 6 Centimeters Thru Water.

This Chart Shows the Paths of X-rays. The Study of X-rays is the Most Recent Field of Electrical Experiments. The X-rays are Electrons, Photographic Plates are Used to Detect Their Presence. X-rays were First Obtained by Paschen in 1895. They are the rays of which X-rays consist of is mostly made up of "betweens." Which is the "between"? Is it Wood or Stone? The Electron Theory and Structure Makes It Perfectly Clear.

The Path shown by an X-ray is entirely independent of the material it pierces. When X-rays fall on a piece of wood or bone, they pass freely through the material, and the image is not very much altered. This is because the X-rays are not absorbed by the wood or bone. When X-rays fall on a piece of iron or steel, the image is much altered because the X-rays are absorbed by the iron or steel. The X-rays are not absorbed by all materials, but only by materials that have a high density. The density of a material is a measure of how much mass is packed into a given volume. The higher the density of a material, the more X-rays are absorbed by it. This is why X-rays are so useful in medicine, where they are used to see through bones and other dense materials.

The distance of alpha particles in air is very short, and they are easily deflected by the lightest particles. The distance of beta particles in air is considerably longer, and they are less easily deflected. The distance of gamma rays in air is very long, and they are not easily deflected at all. This is because gamma rays have a very high energy, and they are not affected by the electromagnetic field of the air.

The distance of X-rays in air is variable, and depends on the energy of the X-rays. The higher the energy of the X-rays, the longer the distance they travel in air. This is because the higher energy X-rays have more momentum, and they are less affected by the electromagnetic field of the air.

The distance of electrons in air is very long, and they are not easily deflected. This is because electrons have a very high energy, and they are not affected by the electromagnetic field of the air.

The distance of protons in air is very short, and they are easily deflected by the lightest particles. The distance of neutrons in air is very long, and they are not easily deflected at all. This is because neutrons have a very high energy, and they are not affected by the electromagnetic field of the air.

The distance of alpha particles in water is very short, and they are easily deflected by the lightest particles. The distance of beta particles in water is considerably longer, and they are less easily deflected. The distance of gamma rays in water is very long, and they are not easily deflected at all. This is because gamma rays have a very high energy, and they are not affected by the electromagnetic field of the water.

The distance of X-rays in water is variable, and depends on the energy of the X-rays. The higher the energy of the X-rays, the longer the distance they travel in water. This is because the higher energy X-rays have more momentum, and they are less affected by the electromagnetic field of the water.

The distance of electrons in water is very long, and they are not easily deflected. This is because electrons have a very high energy, and they are not affected by the electromagnetic field of the water.

The distance of protons in water is very short, and they are easily deflected by the lightest particles. The distance of neutrons in water is very long, and they are not easily deflected at all. This is because neutrons have a very high energy, and they are not affected by the electromagnetic field of the water.

THE present article which closes our contest on Burnt-Out Lamps illustrates that the idea has not been entirely exhausted. Since we published the results of our last contest in our June, 1918, issue, we have received over two thousand more suggestions from contestants located practically all over the world. Most of these of course were duplicates, and were along the lines of the ideas which we had published in former issues or otherwise were variations of them. There were all kinds of fantastic ideas, and we give below a few of the suggestions which came to the editor's desk but which were not of sufficient importance to warrant publishing separately. Among these were the following: Gold fish globes, a sort of steam turbine, stocking darning, cord (ball) holder, a swimming device, an apparatus to catch fish, and last but not least, a transparency representing the Kaiser to be shot at with a gun.

Perhaps the most original one which we publish here comes from France from M. G. Mohr-Desforges, Roulet, France. M. Desforges, who serves in the French army, has evolved a really good battery which we are pleased to illustrate and describe in full herewith. While it cannot be used for lighting or similar work, forty of them would certainly make a very fine battery for audition circuits, while it is for measuring work, etc., the Meiding battery can hardly be surpassed. Of course, all copper sulfate batteries must be used on a closed circuit, they cannot be left on open circuit.

MEIDINGER BATTERY

This idea is submitted by M. G. Mohr-Desforges, Sapeur Télégraphe, 8e Génie, 8e, D/T Détachement, Armée d'Orient, Roulet (Charentes), France. It is a very clever design of a Meidinger type battery with two solutions. This battery is well-known in Europe and America. It works automatically. It must be used on a closed circuit, open circuit work not being permissible. M. Desforges constructs his battery as follows:

A large burn-out lamp globe is cut in the top to accommodate another similar globe as shown in our illustration. After removing the glass stem of the lower globe, a small copper tube is soldered to the former filament; connections as shown. This forms the positive pole of the battery. From the stationary globe is suspended a zinc cylinder made of sheet zinc of suitable thickness and about in proportion as shown, which is suspended from the globe by means of wires. These wires may be copper, but in order to safeguard against local action, they must be well painted with asphaltum before being inserted in the solution. One wire forms the negative pole.

The other globe is filled with copper sulfate crystals and the open end is closed by means of a paraffined cork thru which a short piece of glass tubing passes. M. Desforges continues as follows: (French translation). "This is how I accomplish it:

I first fill one-third of the lower globe with a 10% solution of sulfate of zinc. Then by means of a glass funnel which must go all the way down, I pour a concentrated solution of sulfate of copper, which being of a heavier specific gravity stays at the bottom and raises the sulfate of zinc solution. A sharp dark blue markantion shows the line separating the two liquids. The lower globe will now be found to be about three-quarters full. I now insert the upper globe carefully, taking care not to shake the liquids which would otherwise mix. The battery is now ready for work. It gives approximately 1.07 volts.

"As the battery works, the copper sulfate at the bottom is used up, but a new supply is always at hand on account of the upper globe being filled with crystals that dissolve very slowly, the resultant solution descending by gravity to the bottom."

A SIMPLE HOT-WIRE AMMETER.

An efficient yet simple hot-wire ammeter can be constructed at small cost from a 100 watt Type "C" lamp. First break off the tip of the bulb, leaving a hole about ½ of an inch in diameter. Insert a forked wire with which to remove the spiral filament, and carefully bend the supporting ribs "B", back so as not to short-circuit the main leads. Next get a piece of No. 32 Manganin wire about two inches long, and solder each end firmly to a six-inch piece of iron wire for a handle. Having first arranged the ends of the lead wires so they are about an inch apart, insert the fine wire and wrap a half inch of each end about each lead, and break off the iron wire. Solder the joints by using a piece of resin core solder as one electrode of a storage battery circuit, the joint as the other, and the current will pass between them. It may be necessary to spread the leads (A) slightly after this operation to tighten the hot-wire. A short piece of No. 14 aluminum wire "D" is hung over the center of "C" and the ammeter is complete. Hang in an inverted position, and a current passing thru "C" allows it to sag, increasing the length of "D" protruding at the tip of the wire.

A useful Hand Grenade Fire Extinguisher.

Make up two solutions, one of part of sulfuric acid and ten parts of water, and a second solution of fifty parts sodium bicarbonate and five parts of water. Break off the tip of one of the show case bulbs under the acid solution and break off the tip of the other under the sodium bicarbonate solution. Close the fine holes with sealing wax. Bind the two bulbs tightly together and when a fire breaks out in the laboratory or elsewhere, just hurl the two bulbs at the flaming place, the two bulbs will burst, their contents unite in mortol contest, liberating much carbon dioxide gas, which will extinguish the flame.

Benson Freeman, Atlanta, Ga.

BATTERY TESTER.

Take a burn-out lamp, it does not matter what kind, and cut the top off with a three-cornered file as shown at left. Also pull out the lead wires. Just above the base of the lamp wind 15 to 20 feet of No. 22 wire. Then take a ½-inch nail and a small bit of cork. File off the nail as shown and cut the cork so that there is just enough cork (Continued on page 471)
Notice to All Radio Readers

As most of our radio readers are undoubtedly aware, the U. S. Government has decided that all Amateur Wireless Stations, whether licensed or unlicensed, or equipped for receiving or transmitting, shall be closed.

It is of the utmost importance that this decision be carried into effect immediately, for the reason that we desire to continue to publish valuable articles on the wireless art from time to time, and which may treat on both transmitting and receiving apparatus. In the first place, there are a great many students among our readers who will demand and expect a continuation of the usual class of Radio subjects, which we have published in the past four years, and secondly, there will be hundreds and even thousands of new radio pupils in the various naval and civilian schools throughout the country who will be benefited by up-to-date wireless articles treating on both the transmitting as well as receiving equipment. Remember that you must not connect up radio apparatus to any form of antenna.—The Editors.

Senatore Marconi Head of Italy’s Banking System

We have not heard a great deal of Senatore Guglielmo Marconi of late, due no doubt to the enormous weight of the several large enterprises and governmental positions of which he is the dominant figure. The recent reports of his activities state that he has been busy to the United States as the President of the American Radio Manufacturing Company, representing Italy. However, his country’s need of him was so urgent as to cause a cancellation of this particular mission. We, in a way, regret this decision as men of Marconi’s caliber are a valuable asset to any nation, locality or city which they may honor with their presence.

Senatore Marconi has rendered a very great service to Italy, and the nations of the world in general, by his abolition of all traces of the Teutonic financial supremacy, which, up to the time that his revision became effective, had been paramount, and the Germans had wielded a very powerful persuasive, namely the capitalization of very nearly all of the large enterprises in Italy. Dr. Marconi originated and organized the new banking system now in vogue in that country, and with him as the “moving spirit” of the undertaking, its future success is amply assured. As an irresistible worker, Dr. Marconi possesses animation, vigor and vivacity, and corrals all prices. He is ever “on the job” whether it be day or night.

He last visited this country as a member of the Italian Mission to the United States, and the photograph which accompanies this note, was taken at that time, when he received fifty young ladies from the Wireless Club of Hunter College, New York. He spoke to these women on their work as an aid to the Government. The highest title Guglielmo Marconi has had bestowed upon him is the one of Senator. He is one of the youngest Italian Senators. A title second in importance is that of Chief of Communications of the Italian Navy. Dr. Marconi is a member of the Institution of Electrical Engineers and numerous other well-known electrical and scientific societies throughout the world. His work has been recognized by many governments and seats of learning; he has been decorated by the King of Italy and the late Czar of Russia; he is an honorary doctor (LL.D. D. Sc.) of many universities, including Oxford, Glasgow, Aberdeen, Liverpool and Pennsylvania, besides having received the freedom of the principal Italian cities. He was awarded the Nobel Prize for Physics, which is perhaps the highest distinction that can be obtained by any scientist. He has also been the recipient of scientific rewards granted by many and various societies and other institutions throughout the world.

RADIO FLASHES 12,000 MILES.

Direct communication with Australia is the latest development of radio-communication.

Connection was established on October 1st, when Commonwealth Premier Hughes and Sir Joseph Cook, Minister for the English Navy, sent two messages to the Amalgamated Wireless Company of Australia at Sydney from the new Marconi station at Carnarvon, Wales, and the distance of direct transmission was 12,000 miles the messages were received with perfect clearness. The Hertzian waves of wireless message move equally in all directions. If, therefore, the messages between Wales and Australia should pass round the globe in one direction, they did so in all other directions, and these messages may be said to have enveloped the globe.

U. S. MAGNETIC SURVEY.

The Magnetic Survey Vessel, Carnegie, arrived safely at her home port, Washington, D. C. on June 10, where she will be put out of commission probably during the period of the war. During her cruise from Buenos Aires, Argentina, round the Horn to Valparaiso, Chile, Callao, Peru, thence thru the Panama Canal to Newport News, she was in command of Dr. N. W. Edmonds; the other members of the scientific staff aboard were: Messrs. A. D. Power, Bradley Jones, L. L. Tanguy, J. M. McFadden, and Walter E. Scott.

DO YOU KNOW?

That hydrogen and ozone play the most important part in your make-up. Your body is more than three-quarters water, the water is two-thirds hydrogen and one-third oxygen.
NEW CUTTER USEFUL IN QUENCHED GAP MAKING

The new adjustable cutter consists of a steel casting, on which are mounted two cutting tools, which may be adjusted to various diameters. This part of the device is rotated by means of a ratchet wrench. Pressure is applied to the cutting tools by means of a heavy coil spring. The device is held in place by a round stud, which is placed thru a ¾” pilot hole in the metal to be cut (in the case of iron conduit boxes) and fastened on the back of this metal by means of a flange nut.

It is obvious that this cutter can be operated in positions that would otherwise be inaccessible.

The old method of drilling a large number of small holes and then punching out the metal makes a crude job at the best and is slow, costly and very laborious. Not only can this device be applied to cutting holes and grooves in steel cabinets, boilers, tanks, etc., but also can be used for cutting metal, such as slate, marble and fibre. It is used for cutting holes or grooves ½” to 3”. The larger size cuts holes from 1¾” to 6”. A still larger size cutter will cut holes or grooves up to 12” in diameter.

A New Cutter which Lends Itself Well to the Making of Amateur Quenched Spark Gaps.

GERMAN RADIO APPARATUS ON AIRPLANES.

Lieutenant Jean-Abel Lefranc, writing in a recent issue of *Nature* on the evolution of German Aviation, states that for some little time the enemy machines have been occasionally equipped with continuous wave receivers of the valve type. Regarding the transmitting apparatus, Lieut. Lefranc says that the generator produces alternating current (270 volts 3 amps.) and continuous current (50 volts 4 amps.) The machine is driven either by a small airscrew rotating at 4,500 revolutions per minute, or by the motor. The alternating current produced by this generator is utilised by the oscillating circuit which gives rise to the oscillations creating the Hertzian waves. The Telefunken sender consists of a rectangular box containing a transformer, a condenser, a plate discharger and a wave-meter. Special arrangements permit of variation of wave length and intensity of transmission.

Radio Outfit on a German Airplane.

The aerial consists of a copper wire approximately 35 to 40 meters in length. On the ground this wire is rolled up on a bobbin. During flight it is suspended from the machine.

The range of these sets is about 35 km. (21 miles) and their weight in all 26 kg. (about 60 lbs.) The latest giant airplanes guide themselves at night by radio-oscillographs, as the Zeppelins do.

It will be noticed from the diagram reproduced herewith that the generator supplies current for several purposes. Thus the leads A go to the electric warming apparatus in the pilot’s clothes; B to the lamps on the instrument board; C to the observer’s clothes; D and E to heating apparatus on the camera and machine gun respectively. F is the searchlight for night landings. All G is therefore concerned with lighting. The generator, while K is obviously the transmitting key. L contains the Telefunken transmitters; M and N and O are the aerial ammeter, the aerial reel and the antenna itself. All Q is the purely wireless apparatus.

NEW METERS FOR RADIO AND HIGH-FREQUENCY WORK.

A high grade hot wire measuring instrument designed particularly for wireless and other high-frequency work, depending for its operation upon the expansion of a metal strip which is heated by the current to be measured has recently been developed. The slight sag in this conducting strip is magnified several hundred times on the scale by means of a combination of wires and a deflecting spring.

The conducting strip is made of special non-corrosive material. The operating posts have the same temperature coefficient of expansion as the conducting strip, so that the changes in room temperature do not cause an error in the reading of the instrument.

The scale plate is made of metal, and the scale subtends an arc of 90 degrees, being 2½ inches long.

The flush-mounting type meters have a guaranteed accuracy of 2 per cent, while the portable type, which can be expected to show an accuracy within 1 per cent of full scale. Standard meters are for 1, 2 and 5 amperes. Care must be used not to subject the instrument to more than 200 per cent load.—Photos courtesy Westinghouse Electric & Mfg. Co.

New High-Power Radio Station at Annapolis, Md.

The new high-power radio station at Annapolis, Md., the most powerful in America, was formally opened recently, Secretary Daniels signalizing the occasion by sending messages to the first lord of the British Admiralty, London; the French minister of marine, in Paris; and the Italian minister of marine, in Rome.

The station completed cost about $1,500,000, and is capable of maintaining uninterrupted communication over a distance of at least 4,000 miles.

There are four steel towers, each 650 feet high supporting the antennae which, with the ground system, required 100 miles of wire for their completion. The power installations is in duplicate, so that it will always be possible to maintain communication. The operation of the station requires the services of 100 men, all of whom are drawn from the enlisted force of the Navy. Suitable provision has been made for the protection of the station.

These messages were transmitted to London, Paris, and Rome with the utmost success, which is especially gratifying to Navy officials, since this powerful plant was erected and equipt by the Navy in the short space of 10 months. Under conditions that prevailed before our entry into the war its erection would have taken two years.
ELECTRICAL EXPerimenter

Bunque

By ALAN C. ROCKWOOD

I recently saw the advertisement of a Chronic Plunge Battery. I don’t know about Chronic Plunge batteries but I’ve certainly had plenty of experience with Chronically Discharged Batteries. A prominent radio experimenter who has wanderings may appear again. The compiler, however, needs some help on the job. If you have any electrical or radio quips send them along. Further decisions will be given or withheld as desired. Address “Bunque” care of the publishers of Electrical Experimenter.

Thank you.

A RADIO ECHO FROM THE PAST.

Mr. Godfrey Isaacs, in the course of a recent address in London referred to the achievements of wireless telegraphy and the progress that had been made in the twenty odd years of Mr. Marconi’s labors. This reference on the part of the Managing Director of the Marconi International Company brought forth a reminiscence from a Member of Parliament which appeared in the pages of Town Topics and is worth reading again.

“It is just twenty years ago since Mr. Marconi, now Senator Marconi, gave an exhibition of his wireless invention to members of the House of Commons.

He wanted to prove that a wireless message could be sent from the Terra...
A Sensitive Wireless Recorder

By ARNO A. KLUGE

NOW that the radio experimenter is taking an enforced "vacation" which may continue for some time to come, altho we hope not too long, perhaps it would not be amiss to attempt the construction of a more difficult piece of apparatus than the ordinary instrument, and yet one which has great possibilities for the operator.

With this thought in mind, I present here, with the details for making an ultra-sensitive relay, one which can be used for amplifying weak radio signals, so that they actuate a tape recorder or an audible buzzer. At first thought this device may seem rather complicated, but with a little skill, patience, and the expenditure of very little money, a suitable relay can be constructed that will rival any in existence.

The principle of this device is that of the capillary electrometer, which was first discussed by Prof. Lipmann several years ago. A "U"-shaped glass tube, A, Fig. 1, about \( \frac{1}{2} \) inch inside diameter, is filled with chemically pure mercury, so that it comes within \( \frac{1}{2} \) inch of the top of the shorter arm. A small quantity of 20 per cent sulfuric acid is then poured in on the top, at B. A plunger, C, carrying an electrode, is inserted in the long arm for varying the height of the mercury, and the whole apparatus is supported by a laboratory standard or a board.

Next we take a small glass tube that will fit inside the large one, and draw one end out into a fine capillary tube, by heating in a Bunsen flame. The bore of this tube at the capillary end should be about the size of a human hair, but it is best to make several different sizes to find the right diameter. This tube should be about two inches long, and is supported directly above the short arm of the large tube, so that it just dips into the sulfuric acid. A small quantity of mercury is then poured into it, connections are brought out at C and D, and the apparatus is ready to adjust.

This is done by blowing in the tube D until a small stream of mercury is forced thru the capillary tube into the acid. The pressure is then released, and, due to the capillary action, the mercury will recede a trifle, and will draw a quantity of the sulfuric acid up with it. The separation between the two mercury columns is now regulated by the plunger C, until the instrument works best.

To test the instrument, it is only necessary to place the moistened fingers across the binding posts, and the difference of potential between the two masses of mercury will affect the surface tension, and cause the point at the junction of the liquids to move up and down. The movement from such a slight potential is very small, visible only with a magnifying glass, but with strong wireless signals it becomes more pronounced, and is visible even to the naked eye.

To apply the instrument in operating a relay or recorder, it is necessary to use a beam of light, as shown by Fig. 2, playing upon a selenium cell, the construction of which will be evident to the experimenter. The same beam of light could also be used in giving a screen demonstration of radio or a photo-recorder could be built, and the signals recorded upon sensitive paper, as the operator chooses.

And while it is not possible to use this device in wireless at present, it has many other interesting uses which will suggest themselves to the experimenter, such as recording the fluctuations of the voice upon the screen, recording the sine wave of an alternating current by means of a revolving mirror, etc.

**BURNED-OUT LAMP CONTEST**

to float the nail. Now fill the lamp with water and drop the cork with the nail in the water. By connecting the two leads of the magnet coil to a battery the cork will go down and rise again as soon as the current is shut off. The harder and faster the cork goes down the more current the battery contains.

EDWARD N. HEURNER,
New York, N. Y.

**Connecting Plug.**

First break away the glass globe down to the brass base of a burned-out lamp bulb, leaving the glass part which holds the two wires. Next solder on the two ends of a flexible lamp cord to the two wires projecting from the glass.

Then take a brace and 1" bit and bore a hole thru a short piece of 2" x 2" wood. Into one end of the hole start the brass base

A French system of rapid telegraphy, by which 40,000 words an hour can be transmitted, has worked successfully for distances up to 900 miles in that country.
Radio amplifiers of many kinds have been tried but in the twenty years that wireless telegraphy has been with us, the more prominent types of current intensifying devices will be discussed here, reference being made to some of the novel or interesting ones. An amplifier is usually considered to be a device acting by electro-magnetic or other law, so as to boost the strength of a received radio signal. Such apparatus is of the greatest importance in radio work, not only for the improvement of weak signals at the receiving end, but also for the control or modulation of heavy radio-telephonic transmitter currents.

The electro-magnetic amplifier illustrated in Fig. 1, known as the “Multi-Audiophone,” is claimed to boost incoming wireless messages fifteen hundred times their original strength into radio signals. The amplifier consists of a special chemical placed between two electrodes, which arrangement changes the resistance by virtue of a diafram attracted to an electro-magnet. This will be more clearly understood by referring to a cross-section view of this instrument, Fig. 1. It consists of a permanent magnet A, supporting a metallic case N, having a threaded screw cap M. The case contains the amplification parts, comprising a condenser set B, a small iron core E connected to a very fine steel diafram D, carrying a cup F upon its surface. Another cup G is placed on the opposite side and connected to it, the chemical is placed at I. A tube H is provided so that the material is retained within the cups. The cup G is connected to a threaded rod J and lever K, supported by a rubber standard L on the steel magnet A. The diafram D is gold-plated in order that the chemical will not affect the steel. The electro-magnet B is connected by means of the wires O, while diafram D is joined to wire P. Rod J connects to terminal Q.

In order to regulate the pressure on the chemical mixture between the cups and electrodes, adjustment is made by nut K.

The action of this amplifier is somewhat microphonic, and as the diafram is caused to vibrate by the current in the condenser, it varies the distance between the electrodes, consequently varying the resistance of the chemical and accords a corresponding current. A 5-ohm ‘phone is used in connection with this amplifier, so it is evident that a large current is used in this secondary circuit. A horn is connected so that the messages can be heard about the room without using a pair of head ‘phones. If two or more of these units are used in cascade, it is possible to such an extent of loudness that one can hardly stay in the room on account of the loudness of the signals. The “Brown” Radio and Telegraph Relay.—The electro-magnetic telephone and telegraph relay designed by Brown, of England, is widely used for telephone current intensifying, and has been successfully employed for boosting radio signals.

Its make-up will be gleaned from Fig. 2, where N S is a permanent steel magnet furnished with one magnetizing coils K, and two, 4,400-ohm coils H (same size pole-pieces, etc., as used in a telephone receiver). A light spring or reed P carries a small armature Q magnetized by the pole-pieces. Attached to the moving reed is a rod joined to a delicate microphone M, filled with polished carbon grains.

The reference to connections in radio circuits we see that terminals A are joined in place of the regular telephone. The magnet coils K are energized by current from a battery of six volts thru the primary (17 ohms) of an auto-transformer P. S. Across the transformer acts or controls the battery thru a second "tuned" reed microphone M, etc. Three microphones are commonly used. Two of these "tuned" amplifiers can receive two different musical messages simultaneously without interference, if they and the incoming waves have a tune frequency differing by 20 per cent or over, it is claimed. Such a telephone receiver is delicate and must be very carefully adjusted and supported on elastic bands or otherwise supported in a shock-proof manner by employing a rubber. The third microphone circuit may control a "loud talker" or Morse tape recorder as desired. These microphones are extremely well built to permit of the most exact adjustment. The resistance of each microphone circuit, as well as the potential applied, is made finely adjustable. The "Detectiphone" and "Detectophone" receive set give a most interesting application of the "Detectophone" or dictograph, in the form of an amplifier for feeble or weak electric currents, as Fig. 4 there is outlined a system which has been tried out and which, when carefully and properly made, will yield good results.

Considering first the regular radio receiving instruments, with aerial A, ground G, loose coupler L (or tuning coil), we see that the regular sensitive and "tuned" receiver R 1, is mounted close up to a "Detectiphone" transmitter. An ordinary detector, finely adjusted, is connected at D, while C is the usual blocking condenser. The detector may be a crystal type or a Radium, which requires no adjustment. This circuit, shown schematically at Fig. 4, is for a 2-stage amplifier, but a 3rd "Detectophone" set gives better results of course. The batteries A and B are the regular ones supplied with the instruments, or they be ordinary 4½ volt flash-light batteries. At T 1 is the first transmitter of a "Detectophone" and its receiver at R 2, T 2 is the second transmitter and its receiver R 3. The only high resistance wireless type receiver is that indicated at R 1. This should be a "phone" and have at least 1,000 ohms resistance, and better, yet 2,000 to 2,000 ohms; so as to be as sensitive to the rectified detector currents as possible. This is a demonstration of the fundamental principle that if a faint sound, such as a radiotelegraphic signal, be reproduced close to the ultra-sensitive transmitter of the "Detectophone," then that faint sound will cause the diafram of the transmitter to vibrate, and thus cause variations in its resistance; which in turn are manifested in the receiver of the first "Detectophone." These signals actuate the second "phone," and this in turn controls the third, and the "Detectophone" receiver R 3, is well to place a 10-ohm adjustable rheostat in series with each amplifying circuit, to enable the battery current to be regulated to any desired strength. This device may be applied in any case to these "Detectophone" circuits.

Several different arrangements and modifications of the apparatus may be made, and thus the experimenter and student is left a good chance for research work along these lines. Stopocks or tuned transformers are probably the most successful, as they may be employed, as well as telephone induction coils, etc.

In making up such an amplifying set, care should be exercised to ensure that the receivers and transmitters very close to each other, each unit mounted in a sound-proof, air-tight wooden box, packed with felt, or other sound-deadening material. This may be done by carefully removing the front threaded.

The Oscillograph—How It Works
By PROF. LINDLEY PYLE, Professor of Physics, Washington University

The oscillograph is one of the simplest yet one of the most marvelous of our electrical instruments,—simple because it consists of a single loop of wire hanging in the air-gap of an electromagnet, and marvelous in that it takes a moving picture of the behavior of an electrical current showing variations occurring in a time interval of one-thousandth of a second or less.

The principle of the oscillograph is made clear by reference to figures 1 and 2. Figure 1 shows an incandescent lamp burning on a 110 volt, 60 cycle A. C. circuit. The carbon filament in this lamp takes the form of a long single loop (hair-pin type). The tip of the lamp is toward the observer and the incandescent filament is clearly observable, along with some bright reflections in the glass globe. The horse-shoe magnet in the illustration is drawn away so that it has no appreciable influence. Now note in Fig. 2 the behavior of the loop filament when the magnet is brought close:—the filament is thrown into a violent twisting vibration. When one leg of the loop moves toward the magnet the other leg moves away, and when the first mentioned leg starts back the second starts forward. It is only necessary to recall that a current-carrying conductor extending across the lines of force of a magnetic field is urged sideways by a force PROPORTIONAL TO the strength of the traversing current. In the case of a loop the current at any instant is in opposite directions in the two legs; the two forces are therefore opposite and the filament is twisted. If the current is reversed the electromagnetic forces change direction and the loop is twisted the other way. The amount of twist depends upon the strength of current in the loop. Since the lamp in the illustration carries a current alternating in direction at the rate of 60 complete to-and-fro oscillations per second, the lamp filament is thereby forced to make 60 to-and-fro twists per second, or 120 single vibrations per second. Now this motion is too rapid for the eye to follow and the incandescent filament spreads out into an apparent ribbon of light as illustrated. So much for the illustration of the principle.

Fig. 1, and 2—Showing the Effect Produced by Bringing a Steel Magnet Close to a Carbon Filament Lamp Operated by 60 Cycle A. C. Magnet Away—Filament Still; Magnet Close—Filament Twisted Back and Forth 60 Times Per Second. This is the Fundamental Principle of the Oscillograph.

Fig. 3. Remarkable Oscillogram Taken by the Author. The Large Curve Shows 1 Cycle of a 60 Cycle A. C. The Small Ripples Show the Record Made by a “Howler”—a Microphone Held in Front of a Receiver—the Ripple Frequency Being 1380 Oscillations Per Second.

Now what is the mirror trying to tell us? Imagine the whole apparatus to be in a darkened room and allow a beam of light from the sun or an arc light to enter the room thru a small hole and to fall upon the moving mirror. The reflected beam of light will sway to and fro in accordance with the movement of the mirror. Take an unexposed photographic plate, hold its face toward the mirror, and chop it down across the reflected beam. Develop and fix the plate and a wavy line will be shown on the plate representing the displacement of the mirror at every instant. This method of registration is easy to understand if one takes a pencil and draws on a sheet of paper a line parallel to the top edge of the sheet. Now while running the pencil to and fro across this line, take hold of the top of the sheet and pull it out from under the moving pencil. The result is a wavy line drawn on the sheet of paper. If the (Continued on page 488)
A Thermostatic Time Switch

By ALBERT H. BEILER

I'll admit right at the start that this thermostatic time switch might better be placed in the E. E. category of "phony patents." If you ask me what real use it has, I can't tell you, but if you are the sort of "bug" who occasionally wants something novel—the commercial use of a thermostat. Also if you try to arrange to cool it, then when R contracts what is to keep the circuit from being opened at C?

Our problem, then, is this: Let a circuit be closed at C after a minute or so by the expansion of R, but as soon as this is done let the heating coil circuit become opened.

When you close the circuit containing this "Thermostatic Time Switch," the lamps connected in it flash up about two minutes later—why? Read the article. It explains just how to make this mystic apparatus.

Further, when R contracts on cooling let it have no effect on the continuity of the lamp circuit.

To accomplish this we will use our old friend the stick relay which the writer described in his article on "Burglar Alarms" in the July, 1917, issue of the Electrical Experimenter. Fig. 3 illustrates the circuit, and the mode of operation is as follows:

M is an electromagnet, one end of whose coil is attached to the core R. is the rod with the heating coil wound on it, W is a water rheostat to regulate the current of the heating coil. T is the time switch, S the main switch and L the lamps. C is the thermostat contact and C' is a rear contact for magnet M.

When S is closed but T open all circuits are open. When T is closed current travels from the + main thru switch S, armature A, contact C', heating coil, rheostat, switch T and back to the negative main. Soon the coil heats up enough so that R touches C.

This off cycle is just what is desired on a sign in order to attract attention. But suppose it were required to light lamps L by the thermostat and keep it lit permanently? That is quite another problem. At first thought it seems that an arrangement as seen in Fig. 2 will solve the difficulty. Here when the switch is closed the coil heats up and after a while R touches C and the lamp lights. Very fine, but meanwhile what about our friend the heating coil? If it is kept on for any length of time it will soon burn itself out and no more
A Water-Jet Blast Apparatus
By Professor HERBERT E. METCALF

O NE of the handiest articles around the laboratory is a blast lamp. Usually it is not extensively used because of the fact that most laboratories are not fortunate enough to be equipped with compressed air, and are obliged to make use of a foot blower to obtain the necessary air pressure. The foot blower has a number of disadvantages, such as giving an unsteady pressure, awkwardness in handling, and deterioration of the rubber back. Also its first cost is considerable. The water-jet blast apparatus to be described costs only a fraction as much as a foot blower, will deliver a steady stream of air, and can be made in a very short time with a little knowledge of glass blowing.

In general the water-jet blast apparatus consists of two injectors, a baffle plate, and a large collecting tube. The injectors are the essentials of the outfit, and, upon their efficiency depends the amount of air finally obtained. A piece of heavy walled glass tubing, about 12 inches long is drawn out in the flame making a constriction about one inch and a half from one end. This constriction should be made so that its walls are as thick or thicker than the original wall of the tube, as otherwise they will break in handling. This is done by thickening the glass tube at the point of the constriction by heating it and pinching it together, heating and drawing out very slowly. The lumen of the constricted portion should be straight and about 2 - 3 millimeters in diameter.

Next plug one end with a cork. Center a very fine flame on the short part of the tube just above the constriction until that portion of the wall is white hot and bending in under the flame. Then blow gently into the open end. A bubble will blow out from the heated portion which may be chipped off. Thus a hole is formed in the air inlet. Another tube is now made exactly like the first.

A piece of tubing which will fit inside the injector tube loosely, should be drawn out into a constriction so that the final lumen of this smaller tube will be slightly smaller than the diameter in the flange of the injector tube. This, if cut in the middle of the constriction, will furnish jets for both injector tubes.

The two tubes are then sealed firmly in the short end of the injector tubes by means of sealing wax. The point of the jet should be as near the construction as possible, leaving only enough distance to allow sufficient air to be carried by the end of the jet.

The large collecting tube should be as long as possible and may be made out of tubing, a bottle or a broken graduate. If a bottle is used the bottom may be cut out by winding a wire around it, saturating the string with alcohol, burning and plunging into cold water. The two large rubber cocks which are used in each end, should be of a size to fit very tightly when forced into the tube. The upper cock is perforated with three holes, two for the injectors, and one for the air outlet tube. The lower cock should have a large hole for the water outlet. This outlet tube should be large enough to allow all of the water to escape. In the apparatus as made, the lower tube consisted of a cut-off test tube.

The two injectors are now put thru their holes and adjusted in their final positions. A large cork will do for the baffle plate. This is to break the force of the water, and to allow the air bubbles to rise in the collecting tube. This cork should have two holes bored partway thru to receive the ends of the injectors, and then a series of small holes around the outside so as to allow the water and air to come out at right angles to the injectors.

The air delivery tube is then put in the top rubber cork, the baffle plate cork adjusted and put on, and the top cork prest firmly into place. The bottom cork with its outlet tube in place is then forced in also. In order that both jets function, a double delivery tube is made from the air delivery connection made with the faucet with heavy-walled pressure tubing. All joints should be wired because of the high pressure caused by the small size of the jets.

On the water delivery tube, and on the air delivery tube, there should be placed adjustable pinch-cocks over rubber tubing. These are very important because without their proper regulation the apparatus will not function. Turn on the water full force. If water rises rapidly and threatens to come out the air delivery tube, the air pinch-cock must be tightened. The back pressure will cause the water to go down. If too much air escapes out (Continued on page 504)

TESTING THREE-PHASE MOTORS FOR CONNECTIONS
By HERBERT J. MALONEY, Engineer.
(Australia.)

Many times electricians working among alternating current machinery are called upon to ascertain whether a three-phase motor is star or mesh connected. Little difficulty is experienced when the motor is of open type, where the wires can be easily traced, but the difficulty arises when they are confronted with a totally enclosed motor with only three connections leads projecting. The method here described is a simple way of tackling the situation by means of a megger and bridge. Wheatstone bridge or volt and ammeters. Between the stator leads is taken; after that is obtained bridge two of the leads and measure the resistance between the two bridged leads. The resulting resistance is half of that obtained by the first reading, it is a mesh connected motor, but if it is more than half or near the result obtained in the first reading, the motor is star connected.

The author used for tests for this article two Siemens 3 H.P. induction motors, one mesh and the other star connected. Fig. 2 shows the motor of star connection with two of the leads bridged. Fig. 3 is Fig. 2 in simpler form; as seen, we have phases A and B in parallel and C in series with them, with a resulting resistance of 1.27 ohms, according to the motor used, which is more than half of 1.72 (see Fig. 1) the resistance before the bridge was placed proving that it is a star connected motor. Fig. 6 shows the mesh wiring with two leads bridged. Fig. 7 is Fig. 6 simplified—phase A is shorted or bridged with phases B and C in parallel. The resistance of which is equal to .44 ohms, which is half of 88 ohms, the resistance minus the bridge. Fig. 5 proves that the motor is of mesh connection. Fig. 4 and Fig. 8 show star and mesh motors respectively, with two leads bridged with volt and ammeters, using Ohm's laws to find resistance (R equals —) and either D. C. or A. C. can be used. A study of the diagrams shows the simplicity of the method.
Experimental Mechanics

By SAMUEL D. COHEN

LESSON VII.

LATHE CHUCKS

The next exercise of importance which the novice should try, is to locate the cutting of shoulders on a piece of work. One way is to mark the actual position and then proceed to cut down the material to the mark and to the required diameter as indicated in A, Fig. 1. To accomplish the same result with better accuracy and speed, the use of the cutting-off tool is employed as indicated at B of the same figure, which shows a typical job with proper dimensions to be turned out on the lathe.

To proceed with the job it is first necessary to obtain a piece-of material one inch in diameter and eleven inches long. Square up both ends by placing the material in the live chuck and using a side cutting tool. Drill a counter-sink hole on the square faces and set stock between live and dead centers, securing material to live center with a lathe dog. Adjust the tail stock center so that the shaft plays slightly on the centers. Fasten the tail stock spindle by binding clamp, and keep dead center well oiled. Mark cutting position on work, starting from dead center towards live center. The cutting-off tool is started about 1/32 of an inch from the finishing line of the shoulder, and kept in position until the required diameter is reached, plus 1/32 of an inch more so as to allow for clean finishing. In this case it will be necessary at first to set the outside measuring calipers to read 17/32 inch. Then with the aid of a diamond-point tool, the remaining stock is cut off. To finish the face of the shoulder, use a side cutting tool. The final step is to measure nine inches from the dead center and set the tool to cut off the stock to its proper length, in this particular case nine inches.

Altho this job seems to be quite simple at first glance, yet ninety-five per cent of the beginners will find it difficult to produce the work with the required dimensions. A great deal can be learned from this job. First and foremost is the use of the cutting-tool, which gives most trouble to the novice; and secondly, accuracy in laying out work to rigid specifications.

While preparing this lesson the writer thought it well to omit giving exercises at this early period and consider that further details on the use of the lathe and other tools should supersede everything else. This was found to be essential in that it is important to know practically everything about tools and their use before it is possible to proceed with building a machined article or work-

Owing to lack of space and the great number of new feature articles we have had to postpone publishing the following articles this month: "Spectroscopy, Methods and Spectra"—Part II—by D. S. Binnigton. "The Secret of the Magnet Poles," by Walter E. Kettering. "A Practical Electrical Photo Printer," by Dr. E. Bade. But these, as well as a host of other "brand-new" features, will all be in the DECEMBER number.

In order that various shapes of work may be held on the lathe, special tools called "chucks" are used. There are many different forms of chucks on the market, depending upon their use. The chuck is one of the handiest tools that can be attached to the lathe, increasing its usefulness many times.

One of the commonest and most used chucks is the so-called self-centering chuck, which is shown in photograph, Fig. 2. This particular chuck has three jaws. However, there are chucks equipped with four jaws. The jaws are usually opened and closed simultaneously by turning the handle which is attached to a screw, the screw being geared to a worm connecting all of the jaws. As each jaw moves thru exactly the same distance toward or away from the center, it is obvious that a drill or any piece of work placed in the jaws will be held directly in the center. For holding twist drills, metal rods, bolts and small castings, these chucks are particularly useful and great time savers. Another type of chuck is shown in Fig. 3. This is called an independent chuck, and each jaw is moved in or out by its own screw, which works independently of the other jaws. In this device the work is chucked by moving the step (knurled) jaws in or out by the screws with which they are controlled, the jaws sliding in the block grooves. The jaw blocks are bolted against the face plate of the lathe, as shown in the figure. A single jaw is shown in Fig. 4. These jaws are adaptable for face plates, also for a great variety of work, and are rapidly taking the place of the larger sized chucks for several reasons. They are better adapted for use, being easily attached to the machine, and may be connected to or taken off the plate by one man alone without the use of tackle.

These jaws are reversible, facing them in or out. The sliding jaw may be quickly run out and turned end for end, also the blocks may be reversed if necessary. The last, but not least, item is their cost, and in this case they are much cheaper than other jaws, as they can be secured to the face plate furnished with the lathe. The independent chuck is very handy, especially in working with irregular shaped articles, and is used for jobs which the self-centering chuck cannot accomplish.

THE HALOGENS.

BROMIN, FLUORIN, AND IODIN

BROMIN: History.

This element was discovered in 1826 by Balard, who obtained and isolated it from the bitter or mother liquor of common salt. It was the last non-metal discovered previous to fluorin and argon.

Occurrence.

It occurs chiefly as magnesium bromid in sea water, and as the magnesium, calcium, and sodium salt in many rock-salt deposits and salt wells. It never occurs in the uncombined state in Nature. Large quantities of this element are produced at Stassfurt, and a considerable quantity is manufactured from the residues after the preparation of iodin from kelp, but the larger portion of our supply is derived from "bittern," the mother liquor of the salt industry. Bromides and chlorides of sodium, potassium, calcium and magnesium are contained in the natural salt brine.

Preparation.

1. For preparation in the laboratory, it is liberated from its most common compound, potassium bromid, by the action of man- ganese dioxid and sulfuric acid, analogous to the preparation of chlorin from sodium chlorid.

2. Br + MnO₂ + 2H₂SO₄ = K₂SO₄ + MnSO₄ + 2H₂O + 2 Br

Uses.—In the free state it is employed in the manufacture of bromides and of many bromin derivatives of the coal-tar compounds. It is also used somewhat in the manufacture of anilin colors. Potassium bromid is employed in medicine, and in the basis of other bromin compounds. Silver bromid is employed extensively in photography, especially for the negative.

FLUORIN: History.

The art of etching glass by means of a mixture of flor spar and sulfuric acid was known as far back as 1670. Many attempts have been made in recent years to isolate this element. In 1886, Moissan, by passing a current of 50 volts and 15 amperes through anhydrous hydro-fluoric acid, cooled to —23 degs., and contained in a U-shaped platinum tube, succeeded in obtaining the free element fluorin, as a colorless gas which has since been obtained in solid liquid form. Fluorin was liquefied by Moissan and Dewar, by utilizing liquid air as a refrigerant, at the temperature of —187 degrees.

Occurrence.

It occurs chiefly as calcium fluoride—Florspar—CaF₂, which is widely distributed over the globe, and as sodium and aluminum fluoride—Cryolite—(Na₃AlF₆) which is found in deposits in Greenland. It has been found in small quantity in sea water, in many mineral waters, in the bones and teeth of man, and in milk.

Properties.

1. It is a thin, volatile, deep red liquid.
2. It possesses a very pungent, stifling odor as a gas.
3. Its specific gravity is 2.99 at 15 degrees.
4. It is intensely poisonous, attacking the membranes, especially the eyes. It burns into the flesh and makes sores difficult to heal.
5. It is soluble in 28 parts of water. Its water solution being commercially known as Bromin Water. It is more soluble in carbon disulfid, alcohol or ether.
6. It freezes at —7 degrees, but rapidly evaporates at all temperatures above that.
7. At 1200 degrees the bromin molecule splits into its atoms. This makes one atom per molecule.

CHEMICAL. 1. Its chemical properties are very much like those of chlorin.
2. It has great affinity for hydrogen, and for metals, with which it forms bromides.
3. When dissolved in water it gradually combines with hydrogen and frees oxygen.
4. Antimony powder burns in bromin as in chlorin.
5. Bromin will not unite with oxygen, and no oxid of bromin is known.

IODIN: History.

In 1811 or 1812, Courtois, a soap-boiler of Paris, observed a peculiar corrosion of his copper kettle during the evaporation of kelp liquor, after crystallizing the sodium carbonat from it. Subsequently he obtained (Continued on page 491)
This department will award the following monthly prizes: First Prize, $3.00; Second Prize, $2.00; Third Prize, $1.00.

The purpose of this department is to stimulate experimenters towards accomplishing new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best idea submitted a price of $3.00 is awarded; for the second best idea a $2.00 prize, and for the third best prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings. Use only one side of sheet.

FIRST PRIZE, $3.00

AN ELECTRIC POULTRY WATERER.
When the family is gone for a long while an electric waterer will come in very handy. A lump of ice may be added in the summer time to keep the water cool. C, is a waterproof box made by putting on about two coats of waterproof varnish. B, is a board 1 inch wide. This is nailed at the sides of the box so that it will extend across the box. The box can be of any width and height.

An electro-magnet is screwed to the bottom of the board B. On the top of this door is soldered a clamp attached to the solenoid. The water pressure will hold the door tight against the hole in the box to prevent leakage. The pan G should be right under the door L.

A piece of heavy wire 7, should be sharpened at one end and stuck into a cork. The rod F, is put in the pan G, with the cork at the bottom. At the other end is fastened a piece of brass an inch long.

A piece of brass D, is mounted as shown so the bottom will be as far below the contact on the rod F, as the pan is deep. The wiring is shown clearly. The pan G, is filled with water; so is the box C. As the water is drunk by the poultry the float F, goes down with the water. Finally when the pan is empty the contact on the rod F touches the fixt contact D—this closes the circuit and the solenoid draws the door L, up, the water in the box C rushes out of the hole in the side of the box which was closed by tin door L and starts to fill pan G. The float F goes up and the contact on the upper end breaks the circuit; the door drops down and the water stops flowing.

One battery is sufficient to run this waterer for a long time.

PHENOLPHTHALEIN POLARITY INDICATOR.
The accompanying illustration shows a very simple and accurate way to make a polarity indicator. Altho there have been many articles on a simple way to make polarity indicators many of them have failed, because they did not prove accurate when a small current was past thru it.

For this indicator, make a 25% solution of phenolphthalein, which can be bought at any drug store or chemical supply house. Then take a carbon filament bulb and file the tip off; pass a wire into the bulb and break the filament as in illustration, and fill the bulb about full of phenolphthalein solution, and seal the tip of the bulb with sealing wax. By passing a current thru the indicator, the wire leading to the positive filament, will give off red bubbles, while the negative filament will give off white bubbles. After the current is shut off shake bulb so

...to the positive filament, will give off red bubbles, while the negative filament will give off white bubbles. After the current is shut off shake bulb so

as to make the coloration about the positive filament disappear. It is then ready to be

SECOND PRIZE, $2.00

USE A "MAGNETIC" TACK HAMMER.
1 ? & 1 ?? that "blankety-blank" hammer! That's the third time!
For the benefit of the reader I will say that the above is not a new form of writ-

ing or sign language, but merely a pleasant way any man has of expressing his candid opinion of the common indoor sport of lay-

ing carpets. For some reason or other, when one tries to indulge in this pastime the hammer has a cute and exasperating prac-
tise of colliding with the thumb or fore-
finger, and the result is far from agreeable.

But here's a little idea that will not make triviality of his ears in horror and bid him better half to "remember that the chil-
dren are around." As intimated by the title, it consists merely in having the hammer head magnetic, which may be done by bring-
ing it in contact with a permanent or elec-
to-magnet, in the usual method of magnet-
ing. The tack will then be held in the prop-
er position, as shown by the sketch, withou-

t the necessity of using either the thumb or forefinger, as heretofore.

Contributed by JOHN T. DWYER.

HOME-MADE POLISHING HEAD.
The sketch above shows a practical "Polishing Head" made of ordinary pipe and pipe fittings. First secure from a plumber the following pipe and fittings:— 3 tees, 2 male-female elbows, 2 nipples 1 inch long, 1 flange and one piece of pipe 5 inches long.

Fit them together according to the accom-
panying diagram, and thread a shaft of the right size 2 inches on each end. A pulley, either flat or grooved is fastened in the middle of the shaft by a set screw. This can be used as a polishing head or a grindstone.

There's a War On—

Wake Up!

Some of the many valuable FREE advantages enjoyed by my students

1. I give each student, absolutely free of cost to him, a fine outfit of high grade electrical tools, materials and instruments.

2. I teach each student soon after he enrolls a special branch of electrical science, so he can begin to make money from the start.

3. And before you finish I will give you also, FREE, additional instruction in a special branch of electrical science, designed to place you absolutely in the ranks of the most successful and best paid men in the profession.

L. L. COOKE, Chief Engineer, Chicago Engineering Works.
The well known Consulting and Advisory Engineer, formerly Member of Engineering Staff of American Bridge Co., Pressed Steel and Milburn Bros., Great International Co., New York, London and South Africa. YOUR ADVISER AND INSTRUCTOR.

BE A CERTIFICATED ELECTRICIAN

Earn $45 to $100 a Week

There is only one thing to it; you simply have to prepare for a real business if you expect to ever get ahead; and I can easily train you so you will soon be ready for a fine Electrical position, if you will only follow my advice and instruction. My system of Instruction at Home, without interfering with your work, is simple and clear yet thorough and complete. A few months snappy training of the right kind will prepare you to earn a good salary and start you on the way to a big success.

I have trained thousands of men and I know what I can do for you. In fact, I know so well that I will Guarantee under Bond to return every cent of your tuition if you are not entirely satisfied when you receive your Electric Certificate as a graduate of my school.

How have other successful men gotten ahead? Not by idly drifting along, but by preparing for bigger things. They have no more brains than you, but they have trained them. You can do the same and soon be earning a fine income.

L. L. COOKE, Chief Engineer.
CHICAGO ENGINEERING WORKS.

DEPT. 20X
441 Cass St.
YOU'RE WANTED!

CATED ELECTRICIAN

You Men of Draft Age Don't delay taking up this course because you may be drafted. That's the very reason you should begin immediately. It is your patriotic duty to make yourself worth the most possible to your country—and to yourself—and of course the trained man with technical education is the one who rises in rank and pay. If you begin at once you may finish the course before you are called, but if not the part you have covered will be a benefit to you. Write me about it today.

What Can You Do as a Trained Man? This is absolutely the day of the specialist. Success in any line depends upon training. What line will you take up? There is no field that offers such a wide range of application such wonderful opportunities for financial advancement and such urgent need for more trained men as Electricity. I can very quickly train you so that you can handle your share of the business of the nation. But it is up to YOU. You must act for yourself. But if you will give me your confidence and your co-operation I will take you along the way to a real success.

The Only School In addition to the fact that I am Chief Engineer of Chicago Engineering Works and can help you better than anybody else, here we have large finely equipped shops where you can come at any time for special instruction without charge. No other correspondence school has such equipment or can make you such an offer.

Special Offer Right now I am giving a big valuable surprise that I cannot explain here, to every student who answers this ad. Be sure to get this. Write today.

FREE LESSONS AND OUTFIT

Send me the Free Outfit coupon at once. Do it now! For a limited time I am making a slashing cut in the cost of tuition and giving each new student a free Outfit of Electrical Tools, Materials and Instruments—Absolutely Free. I will also send you—a free and fully prepaid—Proof Lessons to show you how easily you can be trained at home to enter this great profession, by means of my new, revised and original system of mail instruction which has proved so successful for my students.

Valuable Book Free To everyone who answers this ad I will mail my free book—"How to Become An Electrical Expert." Write for it today.

Tear Off and Mail The Coupon Now! It will not cost you a nickel to find out all about this, and it may mean everything to your future life. Don't neglect it. Tear off the coupon right now. Fill in your name and address and send it to me. Then what I will send back to you will show you the wonderful opportunity I am offering you and how easily you can take advantage of it. Now tear off the coupon.

FREE "OUTFIT" COUPON

CHIEF ENGINEER COOKE, Chicago Engineering Works, Dept. 20X-441 Cass Street, Chicago, Ill.

Please send me at once—fully prepaid and entirely free—complete particulars of your great offer for this month.

BE A CERTIFICATED ELECTRICIAN

Never before has there been such a big demand for trained graduate electricians, and at such splendid pay. There are not enough trained men in the country. More men must be trained to meet this urgent need. Here is your opportunity! You—yes you—are wanted, but as a trained electrical man. In these days there is no place for idlers, and there is no place for the untrained man. In civil or military life he is not only useless, but he is a burden. It is now up to every one of us to prepare to be as useful to the country as possible. And after the war the untrained man will be up against it still worse, because he will be unable to compete with the skilled men now being trained. How does this hit you?

ELECTRICAL OPERATED TOY STEAM ENGINE.

The accompanying sketch shows how to operate a model steam engine by electricity.

PROCURE a firm rubber plug the size of the water hole in the boiler. Bore two small holes thru it, then force two pieces of copper wire thru the holes—No. 20 B. & S. will do. Fill the boiler about half full of water, then insert the plug in the water hole so that the ends of the wires will be about one-half inch in the water. Have the wires as close together as possible without letting them touch.

Connect the protruding ends of the copper wires to a transformer that gives 25-30 volts, switch on the current and the engine will run as good as if a spirit lamp was used to heat it. The resistance of the water between the two wires will, of course, cause the water to boil and therefore generate steam.

By using this method and starting with cold water I have had steam up and the engine running in two minutes.

Contributed by A. E. WOODHOUSE.

A "PUSH-BUTTON" LAMP SOCKET.

Secure an ordinary wooden push-button and remove the button, inside contacts, etc. Enlarge the hole in the front so as to admit the socket part (base) of the lamp and fasten it in place with a little sealing wax.

Next pass the wires thru the base of the push-button and screw it to wall. Solder the wires to the base of the lamp, and fasten the two parts together by screwing on to the base.

Contributed by HORACE C. LEEDS.

ELECTRIC DOOR ALARM.

This device can be made of material found in every amateur's junk box. The materials needed are: 2 switch jaws (one drilled), 2 binding posts, and a right-angle triangle of any material. Size is left to the maker. This door alarm will ring if the door is moved, even if only one inch, and won't stop its noise until the proper concealed switch is thrown off.

Contributed by H. PIERRIS.

EXPERIMENTAL ARC LAMP FROM SPARK GAN.

Wishing to pass on a little idea to fellow experimenters I respectfully submit the following:

Any one possessing a spark gap such as in Fig. 1 can make a good experimental essentially of an ebonite rod A which, while being pushed down by means of the button B, is rubbed against cloth placed at E, in a frame of polystyrene disks. During the subsequent rotation the charge thus produced is collected on the brass tube D, insulated by the ebonite collar E. This tube remains, on the other hand, in permanent connection with the piece FF, consisting of two coaxial cylinders and moved together with A. When the rod is at the end of its path a small finger G lightly touches the support of the leaf to be charged. By repressing the pressure on B the spring H brings the rod to its original position, simultaneously connecting F with the brass disk I, and consequently with the electroscope case. The discharge being done consistent with the capacity of the leaf support, things are easily adjusted so as to produce a convenient deflection of the leaf with a single push of the button. A good plan is to overcharge the leaf a little and to keep the button down until the system has discharged itself to the desired point.

HANDY QUICK THROW SWITCH.

Here is a switch of novel design allowing quick changes and at the same time is well constructed, besides being very easy to insulate. As will be noticed it works on the UP and DOWN-ward movement, the blade revolving near the handle on a shaft secured to two wooden or other posts. Two blades or even three could be used.

A PRACTICAL HYDROGEN SULFID GENERATOR FOR THE CHEMIST.

BY K. BURNETT

Hydrogen Sulfid is an absolute necessity in every laboratory where analysis is carried out, but, as this gas is quite poisonous and, furthermore, possesses a characteristic, disagreeable odor, it is essential that it be generated at the time of using.

Below is described a simple generator of my own design, which, from my experience, has proved a complete success. As will be seen, the action is essentially the same as in the well-known "Kipp", but, as the construction of this differs somewhat from my own design, I have found it necessary to add certain additional parts.

The materials needed are:
1. Wide mouth glass bottle G.
2. Gas cylinder.
3. Tube (6" x 1" diameter) made from narrow bottle.
4. Atomizer bulb.
5. Glass tapers, or pinch cocks.
6. Rubber corks to fit tube, cylinder and bottle.
7. Thin one-holed cork (to hold FeS in tube).

Rubber connections and glass tubing.

Chemicals:—Ferrous sulfid.
Hydrochloric acid.

The essential working of the generator is as follows:

When tap A is turned (see figure) the acid rises in tube B, coming in contact with the ferrous sulfid, thus generating hydrogen sulfid gas, which, passing thru the wash bottle C is purified and escapes at D.

Use of the Bulb.—The pressure in tube B required to overcome the counter pressure exerted by the water in the wash bottle is often strong enough to force down the acid in tube B, and thus from further contact with the ferrous sulfid. The result is "no gas". Upon squeezing the bulb, however, the pressure is overcome and the acid rises in tube B, thus forcing out the gas. I have proved this in practise. It is essential that a bulb having an air inlet is employed, otherwise it is useless.

Use of the Pinch Cock F.—In order that the acid may rise in tube B it is necessary to open the pinch cock F to admit air. This is also necessary, when shutting off the generator, in order to expel air, but it should be kept closed when the acid has reached "low level", to prevent rise in case of leakage or lessening of pressure, due to the hydrogen sulfid dissolving in the acid.

Any amateur chemist may set up this apparatus without much expense and I am confident, that, if constructed upon this plan, it will give no trouble and the result is an odorless and convenient generator which makes a fine looking piece of apparatus for any laboratory.

HOME-MADE DISTILLING APPARATUS.

The accompanying sketch illustrates a home-made Distilling Apparatus. The condenser is made from a student lamp chimney. Insert a cork at both ends and bore them for glass tubing. Tube A should extend straight thru the condenser; tube D should extend about an inch below the cork. I found that if tube D is cut off about four inches below the bend and a long piece of rubber tubing used instead of a long glass one it would cost less and be more serviceable. Tube C should extend about 1 inch above the bottom cork. The condenser is held in place by a piece of wood, shaped as in Fig. 2, fastened on a shelf above the bench.

The boiler K is an empty coffee can. A hole is cut in the cover and the neck of an empty maple syrup can is soldered over it. The cover is then soldered on the can so that the steam cannot escape. Three pieces of tin are next soldered on to form a support.

Another can L is fitted with a small faucet which can be obtained off an old gas jet. This can is supported on legs like the boiler. Care should be taken that the bottom of the can L is on a level or higher than the top of the condenser.

When the water boils in can K, the steam passes thru tube A. The faucet on can L is turned on; cold water flows thru tube C and circulates thru the condenser and flows out thru tube D into a sink or a large pan. The distillate is caught at E.

If, when the water is turned on, the lower cork leaks some melted paraffin should be poured slowly into the tube and allowed to harden. This may be done on both sides of the lower cork.

If anything besides water is to be distilled a glass flask must be used instead of can K.

"Amateur Electrical Laboratory" Contest
THIS MONTH'S $3.00 PRIZE WINNER—ELLIOTT C. WOODFORD

I PRESENT herewith three pictures of the chemical laboratory that Eugene Cortright and myself are using at the present time. One of the photos (top center) shows the chemical cabinet containing over two hundred and fifty chemicals, all labeled and arranged in alphabetical order. This photo shows Eugene Cortright standing at the left of the cabinet, and yours truly at the right. Another photo, figure 1, shows the shelves of chemical apparatus, including burettes, crucibles, evaporating dishes, Florence flasks, Erlenmeyer flasks, funnels, graduates, mortars and pestles, retorts, wash bottles, condensers, hydrometers, beakers, U-tubes, and chemical thermometers. To the right of these shelves is the medicine cabinet, and below the medicine cabinet is a soapstone sink with hot and cold water. Another table contains a ring stand, gas tap, Bunsen burner, rack of test tubes, gas mask, and electric tap. Also a compound microscope. One of the tables contains a chemical balance, a ½ K.W. transformer, condenser, and spark gap (part of the wireless station that we had at one time, but which is dismantled now), and which material we intend to use in building an X-ray apparatus. Our stock cabinet contains extra test tubes of different sizes, pipettes, glass tubing, rubber tubing, electrical supplies such as switches, fuses, bulbs, sockets, and adapters, ad lib, ad infinitum.

ELLIOTT C. WOODFORD, Owego, N. Y.

HONORABLE MENTION—MILFORD H. COHEN

ABOUT four years ago, being interested in Electricity, I started a small experimental shop, which I have by the dint of hard work built up to quite an efficient electrical and chemical laboratory. I have an arc light which throws a beam from a mile to a mile and a half. I have constructed many, but this has been my most successful one. A choke coil is used for its resistance which has proven very satisfactory. When battery current is necessary I have a one-eighth horse-power motor, which drives a small fifteen-volt D. C. generator, and this supplies ample current. I also have an old-style graphophone, which plays the cylinder style records; with this graphophone I secured a recorder, and a few blank Dictaphone records. This outfit is excellent in receiving wireless messages coming at a fast rate of speed, for as soon as the message is completed, the reproducer may be changed, instead of the recorder, and in this manner the message may be repeated at a slow rate of speed. This was before the wireless stations were dismantled by our Government, of course. On the side wall of one of the photos (lower group) you will see a very efficient electric furnace, from which a very high degree of heat may be obtained. I am now engaged in making an auto, which is to be driven by a Smith Motor Wheel. My shop is very handy in many other ways, as it allows me to construct various models described in The Electrical Experimenter. In my chemical laboratory I am also doing some very interesting experiments.

MILFORD H. COHEN, Charleston, W. Va.
Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daft inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $30.00 as a final fee. That's $40.00! We PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43,001! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner: THE MOTORMAT BURGLAR EJECTOR. Herewith witness my idea for an electric motormat burglar ejector, guaranteed to work without a hitch in 101 per cent of all cases. Mr. Burglar approaches the stoop and on his first attempt depresses the electric alarm bell button indicated in the S.E. corner of the map. You've got me, Steve! The knight of the black-jack hits the button—the bell rings—the householder (he, she, or it) arises and sneaks up to the front door—beholds intruder on motormat and does his duty by throwing the motor switch. The result is illustrated at the right. I said it was 101 per cent efficient—the extra 1 per cent is the time it 'gets' you, when wife sees you first as you rise up the front stoop about 3 Q. M. in the morning after the night before. Take a tip, Brother Yelps, wear a shock absorber—you know where! Inventor, Wm. A. Fritsch, Brooklyn, N. Y.

Theater-Chair Power-Plant. Did you ever stop to think just how many million horsepower of free energy are dissipated every single night by the thousands of theater-goers in such a large city as New York, when they sit down and get up? It amounts to something like 49,580,666 3/4 H. P. per evening for New York City alone, according to my figures. So, hence and thus, I collected my brains together and eventually devised the astonishingly simple chair pump and dynamo plant here shown. Each chair is connected by a lever with a water pump under the floor. The pump sucks water up from the tank below the water-wheel, forces it out thru another pipe back to the supply tank above the water-wheel, etc. The same water is thus used over and over again. The water-wheel drives the dynamo, which charges a storage battery. Thus the electricity required for lighting up the theater, "movie" machine, etc., is all provided by the unsuspecting audience. The manager gets his money's worth and the Public is pleased!! Inventor, Paul Austin, Phoenixville, Pa.
The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be publish. Rules under which questions will be answered:
1. Only three questions can be submitted to be answered.
2. Only one side of sheets to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addres to this department cannot be answered by mail free of charge.
4. If a quick answer is desired by mail, a nominal charge of 25 cents is made for each question. If the questions entail considerable research work or intricate calculations a special rate will be charged. Correspondents will be informed as to the fee before such questions are answered.

MAKING SOLENOID MOVE ALONG IRON BAR.

(969) W. Doherty, New York, N. Y., sends us a proposed scheme for creating axial movement of a solenoid along an iron bar and wishes our advice on it.

A. 1. To our best knowledge, there is no practical way of getting motion on traveling of the solenoid along a straight iron bar in the way you show in your diagram,

![Diagram of solenoid moving along iron bar]

(see sketch "A"), but it is possible to accomplish this by simply having the iron bar slightly tapered (sketch "B") and you will find a very long treatise on this very subject given in U. S. Patent No. 1,248,273, copy of which we can supply at 10 cents. The Electrical Experimenter for February, 1918, page 90, contains a brief digest on this interesting patent.

CAN HIGH VOLTAGE ALONE KILL?

(960) W. A. J., New York, asks:
Q. 1. We ask you to kindly answer the following question, in order to settle a dispute between two friends:

A says that a wire charged with 75,000 volts of electricity, without a fraction of an ammeter in it, would kill a person touching it. B says that aloft the wire is charged with 50,000 volts and there is no ammeter in it, and that the least part of an ammeter in it, in that a person touching it would not be killed.

We have asked several persons about this matter but in view of the fact of their varied answers we have decided to let yours be the last word. We would appreciate it very much, therefore, if you would kindly inform us what the effect would be on a person touching the wire. In case it would kill him we would also like to know if the killing would be instantly, gradually, or finally.

A. 1. In the first place it is impossible to have a wire charged to 75,000 volts without a fraction of an ammeter in it. You cannot have voltage without amperage and vice versa. In order to kill a person a good many conditions are necessary. It has happened repeatedly that people who touched wires charged to 100,000 volts were not killed, while others took only a 110 volt current and were killed instantly. The point in contact with the human body makes all the difference. For instance, when the hands are wet, the effect will be much more pronounced than if the hands were dry. Also various people have various thicknesses of skin, and the thicker the skin the more it protects. Thus, workmen using pick and shovel after a while acquire a very thick skin on the inside of their hands which forms a protection against the electrical current. Therefore, you will see that just touching a highly charged wire without knowing all the other surrounding conditions itself is meaningless.

Speaking generally, it is not volts that kill, it is the amperage. High voltage by itself is not dangerous as you can take several hundred thousand volts thru the body by means of the so-called Tesla high frequency currents without feeling anything whatsoever. Take an ordinary violet ray machine—it gives a voltage usually above 50,000.

Nor is it necessary to use high frequency currents. Large spark coils which give a tremendous amount of voltage while dangerous are not often fatal to the human system unless a charge is taken into a vital part of the body. The editor has seen a man get a fairly good charge in both hands from an eight-inch spark coil giving somewhat over 300,000 volts (maximum or peak value). While it threw the man down, the effect was not fatal. He recovered in a few minutes without ill effects.

AUTOMATIC AIR PRESSURE REGULATION.

(961) M. B. Pedersen, Tooele City, Utah, writes:
Q. 1. How can I rig up an automatic air compressor regulator so that the electric motor driving the compressor will start and stop at low and high pressure.

A. 1. In the diagram a front view is shown of your air pressure gage. It will be noted that there are two adjustable arms, A and C, which can be regulated for any pressure by means of an adjustable finger, also shown in diagram. These arms, A and C, should be fitted with suitable contact points. They should be insulated from each other, and should be properly connected to external relays for starting and stopping the motor. The point of relieving pressure also have a contact point on it and a connection to an external circuit, as shown in diagram. This scheme has been used successfully for more than two years.

SPONGY PLATINUM.

(963) Sylvan D. Rolfe, Philadelphia, Pa., writes:
Q. 1. Questions on spongy platinum.
A. 1. You are right relative to the matter of spongy platinum. It will only in-
Send for this free lesson which explains the Chicago "Tech" method of teaching Draftsmanship by mail. Positions at big salaries are now waiting for competent men. The call of men to the war has left vacancies everywhere. Even draftsmen of limited training and experience are snapped up and paid good salaries. If you are dissatisfied with your opportunities, learn Draftsmanship. Chicago "Tech" will train you in the most practical way in the shortest time. Mail the coupon today and let us tell you about the Chicago "Tech" method. This free lesson will show you how well equipped you are to follow Draftsmanship. Enroll in the course only if you decide that you can take it up to advantage. No cost, no obligation on you to make this investigation.

Come to the College or Learn At Home

Hold your present position while training. Our experts will instruct you by mail. Only your spare time is required. You are directly under practical draftsmen and engineers. You are taught exactly the work required in the drafting rooms of big concerns. No time to put in on unnecessary studies. This means thorough instruction and early graduation.

$25.00 to $100.00 a Week

Draftsmen earn good salaries in normal times. They command extra high salaries now—and the tremendous work to be done after the war will bring a permanent and intensive demand for good men. Make your spare time count now for a higher salary and a better position.

Easy Payments

The fees for Chicago "Tech" Courses are very moderate—and you can pay on easy terms. And also—you obtain in a few months what it would take several years to acquire by ordinary methods. You can get an early start. You are soon ready to take a paying position and to quickly get back the cost of your course.

Send the Coupon

You are the sooner you are prepared the sooner you will be holding a job that pays a large salary and opens the way to advancement. Many executives, general managers and superintendents began as draftsmen.

Other Institutions ask you to pay first—and then to find out later how well qualified you are for this profession. We send the free lesson first and place you under no obligation at all. Discover your qualifications before you pay anything.

The coupon will bring the Test Lesson, free. Also information about the profession of Draftsmanship and detailed facts about Chicago "Tech" methods, the fees, terms, etc. Mark X the branch you are interested in—or if in doubt about which course to take, write a letter stating facts about yourself and asking our advice which will be freely given. Mail either the coupon or the letter today.

FREE Instruments

Every student of the Chicago "Tech" Course in Draftsmanship receives this set of instruments, or a cash credit in case he already has a set. These instruments are of the same make and sizes as used by high salaried experts in drafting rooms of factories, shops, roads, etc. You use them while learning—they take them right into your practical work.

---

ELECTRICAL EXPERIMENTER

THE ORACLE.
(Continued from page 486)

The patient's faith in the presence of two or more gases, which rapidly combine, and the incandescence is due to the liberation of heat thru the combination of the gases, in which case the action is accelerated due to the presence of the atomic platinum, which acts as a catalytic agent.

EXPERIMENTAL MECHANICS.
(Continued from page 477)

where it is necessary to obtain a central point, irrespective of work. A dog-chuck is one containing independent jaws. Many lathes are supplied by the makers with a four-jaw chuck of this kind.

NOVEL X-RAYS.
(Continued from page 454)

"What are these branch-like marks at the upper and lower side of the skull?"
"Evidently something 'flashed' thru my mind just then—perhaps the birth of an idea. The plate recording the flash, which is just like a flash of lightning."
"How is it that your brain does not show at all?"
"As you know the X-ray picture was taken immediately after I concocted next month's cover design. All my brains went into making that, which explains the discrepancy!"

X-RAYS IN TUBERCULOSIS.

In the finished positive photographic print, the lungs of a normal person show white—this represents air contained in the cells of the lungs. If the lung is diseased—as in pneumonia—it will show dark, i.e., the cells being occupied with matter. Tuberculosis is diagnosed by the spotted, motiled appearance of the affected lungs.

In our illustration here shows clear case of incipient tuberculosis, the arrow's point to the seat of the disease. In this print the patient's right is left, and right is left. The right lung, which is quite dark, except for some free filtration shows traces of tuberculosis as well. In this lung, beginning right under the last lower arrow, we note a semi-circular bulge: this is the lower part of the heart. Underneath the heart is the diafragm—the part dividing the chest from the abdomen.

Photo courtesy Dr. B. Fidler, N. Y. C.

THE OSCILLOGRAPH—HOW IT WORKS.
(Continued from page 474)

paper be pulled at a known rate (say one inch per second) one can study the history of the movement as recorded on the motion in time. Similarly if the photographic plate in our imagined experiment be moved at a known speed, we can then study variation from instant to instant of the current traversing the loop. If the plate be chot thru the beam when no current passes thru the loop and then, with the test current on, chot thru again and in the same place as before (using guides to make the plate follow the same path) then upon development of the plate we will have from the first operation a straight line (the so-called zero line) and from the second operation the current, and thus the variations occurring in the test current. Where the curved line crosses the straight line the current is zero and is changing direction.

Figure 3 represents a record taken by the writer with a modern type of Dudell oscillograph. The prominent wavy line shows the variations occurring in a complete cycle alternating current. Figure 3 is a print from the film negative, the film having moving at the rate of 111 inches per second. The curve takes from the smooth sine curve usually used to represent the alternating current. Just one cycle is represented. What happened in figure 2 took place in one-sixteenth of a second. Certain kinks in the curve do not last longer than 1/2500 of a second. No zero line is recorded. If it were it would be practically impossible to have the time between the upper and lower peaks of the curve. The other smaller curve or ripple of Fig. 3 represents the current fluctuations in the higher order of a sine wave which when the receiver is held against the mouth-piece of the transmitter and is thereby made to emit the familiar high-pitched note gives the device its name the—holer. Note the broad zero line recorded in this curve. This, too, is an alternating current, tho of very different shape from the 60-cycle one. Further, it has a much higher frequency. Reference to the figure shows that 23 cycles of the high frequency current take place during one cycle of the primary current. In other words this howling telephone receiver was traversed by an alternating current of 1360 oscillations per second.

THE GYRO ELECTRIC DESTROYER.
(Continued from page 465)

fact that some of my friends here in the office would like to subscribe to this fund. I am, therefore, enclosing $1.00 to be used in this great idea of you understanding this dollar is not to be credited to me, but to O. H. King, 1422 Hunt Blvd., Atlanta, Ga., that will enable him to work the Destroyer until I go to the Navy, which I am expecting to do in November." . "A. L. Terry.

"1422 Hunt Blvd., Atlanta, Ga."

"INVENTORIALS" AND A "HUMDINGER."

"I have long been a reader of the E. E. and have always maintained a state of mental equilibrium and persuading you sometimes far-fetched 'inventorials' but I must admit that the September number contained a humdinger in the developments of the Gyro-Electric Destroyer. And in some instances it is felt privileged to put up and say "Shake!" to the originators of the idea and the editor who projected it. Why not a Gyro-Electric Destroyer more practical than the first airplane seemed to us, or the first airplane to the last steamboat? So, I say, for it, write some of those advertisements. Like you do! What else? 'Humdinger!' or like your August editorial, which, by the way, was a masterpiece. Keep it up for 18 months if necessary, appeal to the American idea of patriotism, and also of taking a chance, and every man who sees it will send in his dollar. Then you have the winter to build it, and in the spring we will see, what, if any, results. Here's to the success of the Gyro-Electric Teufel-wagen," and 'hoping with a dollar bill."

"Arno A. Kluge."

"12137 St., Lincoln, Neb."

FROM "TOM" REED.

"Good luck, old top!"
"19 Congress St., Boston, Mass."

MORE DOLLARS COMING.

"I will try to interest my friends in this 'Kaiser Killer' and send you some more dollars soon."
"Milton Ward."

"GIVE THEM HELL."

"I am enclosing one dollar as my part of the subscription for the big Gyro-Electric Destroyer. I am not a subscriber to the Electrical Engineering but I purchase my copy as soon as it appears on the newsstands and have read with the greatest interest your article on the Gyro-Electric Destroyer. I am sure this is an interesting and promising idea. Surely subscribers to an "Electrical Engineering" like yourselves will be interested in the Gyro-Electric Destroyer and will with confidence enough to finance one of its experiments. I send away for the Gyro-Electric Destroyer. The Top with the best luck and give them Hell."

"Karl F. Meyers, "Littlestown, Pa."

U. S. AIRPLANE Mail Service  

Started May 15, 1918

marks the real beginning of commercial aviation. Uncle Sam is carrying mail every day between New York, Washington and Philadelphia and the end of the war will make possible the extension of airplane mail delivery to all parts of the country. As fast as machines can be built they will be put to work carrying freight and passengers. But the demands of commerce must wait. Every man who knows, not merely how to make one small part of an airplane, but who has studied and learned the scientific principles of design and construction is needed RIGHT NOW to help win the war.

More Men Needed  

AVIATION

Wonderful salaries are being paid to trained experts in airplane building, airplane assembling, repairing and adjusting. Here is an easy road to promotion or to a splendid paying position in the private employ of one of the scores of airplane manufacturing companies. We have more calls for men than we can supply. Never has any industry offered so many golden opportunities for ambitious men. Make it your business to investigate first before you decide. But don't wait to send for full information.

FREE  

NEW BOOK—"OPPORTUNITIES IN THE AIRPLANE INDUSTRY.”

Just published and mailed free on request—the first complete story of the recent remarkable development of the airplane manufacturing business and the wonderful future it holds for you. Get a copy and read it. Let your friends read it.

Mail Coupon--QUICK

No obligation of any kind. But the edition is limited. Send us your name today, before it is too late, and avoid disappointment.

10 CENTS

CORE WIRE

We have been fortunate in securing thru auction several tons of guaranteed pure, double annealed Norway Iron Core Wire and are selling this wire to "Experimenter" readers at PRE-WAR PRICES 20cts LB.

This wire is just the thing for spark coils, transformers, etc. and it is, of course, a very much more superior product than the usual iron wire. We absolutely guarantee the quality.

If you ever thought of building a spark coil, transformer, or similar apparatus, now is the chance to get the right material at a price you can afford. This is the only lot of Iron Norway Core Wire in the hands of any dealer at the present time, and none can be gotten until after the war.

We only have these three sizes:

24 INCHES

26 INCHES

36 INCHES

Thickness about No. 21 B and 8

If either of these sizes should be too long we advise cutting the wire down yourself by means of shears. It will pay you to do so as normal Norway Iron Wire, sold by a few dealers last year, brought from 40c to 50c a pound. American core wire now sells for from 30c upwards per pound.

As long as the supply lasts we offer this wire as described above to our customers at the very low price of 20c a pound. Order at once.

How Quickly Can You Learn These Words In PARAGON Shorthand

Paragon Shorthand is written phonetically. For example, the word "Day" is written "Da"—the y being omitted.

It's Fascinating! Try It! See Trial Lesson. Your name, address, and the number of characters used in writing these words in Paragon Shorthand is estated on the inside of the flap. We will send you a copy of the Paragon Shorthand text for your own examination, study and approval for 7 days free of cost to you. Use it just as if it were your own, and if, at the end of the 7 days, you are not perfectly satisfied, return it to us and you will see nothing.

Try This Lesson Now

<p>|</p>
<table>
<thead>
<tr>
<th>Paragon Shorthand</th>
</tr>
</thead>
<tbody>
<tr>
<td>75</td>
</tr>
</tbody>
</table>

Take the ordinary long-hand letter A, eliminate the long stroke, and there will remain —

This is the Paragon symbol for D. If it is always written downward.

From the long-hand letter C, rob out everything except the upper part of the circle — and you will have the Paragon E.

Write this circle at the beginning of every line and you will have Ed.

By letting the circle remain open it will be A. Thus $ will be Ad. Add another A at the end thus $ and you will have a's.

From O — eliminate the usual final strokes and O will remain which is the Paragon symbol for O.

For the long-hand 75c which is made of 7 strokes, you use this one horizontal stroke —

Therefore, 75c would be Me.

Now continue the E across the M, so as to add D — thus Me and you will have Med. Now add the large circle O and you will have Med, which is meadow, with the silent A and W omitted.

The long-hand letter N which has 5 strokes, is written in Paragon with one stroke, thus — same as the letter M, but shorter.

You may send the Complete Course of PARAGON Shorthand with the directions under which it is established that I have 7 days after the receipt of the Paragon Shorthand to either remail the Course to you of send you $5.

EXPERIMENTAL CHEMISTRY.

(Continued from page 475)

violet vapors on the addition of sulfuric acid to some of the waste liquor. Davy and Gay-Lussac both investigated this new element a year or so later, and Gay-Lussac gave it the name iodin from the color of its vapors.

Occurrence.

Iodin does not occur free. Its compounds are widely distributed but are not abundant, being found chiefly in combination with sodium, potassium, calcium, and magnesium, in the sea water, salt lakes, and in the sodium nitrate—Chile Salt peter—deposits of Chile and Peru. Until a short time ago the main source of this element, which was seaweed, but now the nitrat deposits of Chile furnish by far the largest proportion.

Preparation.

The seaweeds are collected and burned, the ash forming what has been known for a long time as "Seaweed Ash." These seaweed are fused to a mass of carbon and as, this mass being then lixiviated with water, the solution evaporated to remove the excess of chlorides, sulfates and carbonates, and the concentrated mother liquor treated with sulfuric acid, which causes a separation of sulfur due to the sulfides and sulfates present. This sulfur and the crystals of sulfate formed are removed and the remaining acid liquor contained in an iron retort, is poured with manganese dioxid, which, with the free sulfuric acid previously added, liberates iodin according to the reaction:

$$2\text{NaI} + \text{MnO}_2 + 2\text{H}_2\text{SO}_4 = \text{Na}_2\text{SO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O} + \text{I}_2$$

The temperature is kept at 60 degrees, which causes the iodin to pass off in vapor and condense in a series of carbenware receivers adapted to the retort for that purpose. Fig. 137 depicts such vessels which are known as Aludels. Any excess of manganese is avoided in order to prevent bromin and chlorin, which are present in the liquor as salts, from passing over and combining with the iodin.

Preparation of BROMIN from Potassium Bromid, Manganese Dioxid, and Sulfuric Acid.

Experiment No. 147.

Pulverize in a mortar about 5 grams of Potassium Bromide, or 10 grams of 2 grams of powdered manganese dioxid, then pour over it the potassium bromid from which they were mixed and set aside, and, crossing the paper, pour them into a flask of about 125 cc. capacity. Have a one-hole stopper for a thistle, which should extend slightly below the bottom of the flask. If there is no side neck to the flask, a two-holed stopper must be employed, containing the thistle tube and a delivery tube, right-angle or straight, the delivery tube, either directly from the side neck of the flask, if one is used, or from (Continued on page 498)
Nature and Science WILL HELP YOU

THE Therapeutic White Rays of the Magic Pain Relieving Lamp bring back health and vigor Everybody knows the sun's rays possess positive health-giving properties. Following Nature's law and with the aid of science you can now possess these marvelous healing properties in your own home with the

Magic Pain Relieving Lamp
"The Light that Heals"

RELIEVES pain without destroying vitality. Absolutely safe. Does away with harmful drugs. You will be amazed and delighted by this Magic Lamp whose Therapeutic White Rays penetrates, heals and soothes sore spots. Relief from pain results the moment you snap the electric light switch. Rheumatism, neuralgia, sore throat, earache, gout and a long list of ailments are instantly eased and relieved. It is invaluable in the treatment of skin diseases. Men famous in the world of medicine endorse and recommend Therapeutic Light. Let the Magic Lamp save you pain.

Send for FREE BOOKLET today! Learn what the Magic Lamp has done for others in hospitals, sanatoriums and thousands of private homes. Don't suffer another needless headache. Send at once.

ELECTRICAL EXPERIMENTER

November, 1918

WHY IS A BLIMP? (Continued from page 453)

end of the horizontal "wings". The fins and rudder lie flat against the sides of the balloon when it is not in the air. Upon ascent the wind blows into the rudder thru wooden scoops, inflates it, and passing upward thru two small pipes, inflates the fins in turn. The time that it takes for this inflation depends entirely upon the strength of the wind.

There is an opening between the balloon and the air-rudder, and consequently, when the wind blows into this rudder, it flows thru it and into the balloon. This air not being able to escape, it is put under a pressure equivalent to the pressure of the wind that is forcing it into the balloon, and which is directly governed by the wind velocity in miles per hour on the outside of the bag.

The pressure of this air in the balloon causes it to expand upward, and this upward expansion in turn presses on the gas above until the balloon strikes a state of equilibrium with that of the gas. Upon the occurrence of any atmospheric change, the balloon takes place as previously and causes the balloon proper to retain its original shape. This maintenance of shape is a very necessary element, for upon its remaining constant depends the ability of the balloon to fly accurately and safely.

The basket is made of rattan, which has been interwoven by following the over and under-lapping method which insures rigidity and strength. Its capacity is two observers. One of these acts as a pilot and is responsible for the action of the balloon, while the other-is known as the observer, and he is especially trained for this very important post. Instruments contained in the basket are of highest sensitivity for determining height, direction of wind, speed, and temperature at different hours, etc. A telescope is mounted on the cross-arms of the heads of the occupants, and due to its unique and patented swivel, it has a range of 360 degrees in any plane. Two parachutes also frame as normal activities of the equipment, as also do a telephone, consisting of transmitter and receiver, instrumenation, a camera, and a pair of binoculars, and last, but not least, a means of protection against enemy air attack in the shape of a modern light-weight machine gun.

Of especial interest is the way in which the basket is attached to the balloon. This method of cross-lacing preserves the swing of the basket to nil, and gives an increased stability, beside absolutely preventing rotary motion of any sort by the basket.

The "Blimp", in reality a dirigible balloon, navigating under its own power, is shown in cross-section for the benefit of the reader. By referring to the symbols in the picture, and then finding their corresponding definition in the caption below it, the writer hopes for a thorough understanding of the actions of the various means and methods employed to conquer the air in this particular type of machine.

The chances of enemy artillery making a direct hit and destroying one of these blimps or even observation balloons, is remote. One would casually think that hitting a balloon by shell fire would be the easiest thing in the world. Exactly the contrary is the case. The main difficulty is caused by the fact that there is nothing to judge the burst of the shell by. From its position where the enemy artillery is firing, nothing can be judged except whether the shells are going straight toward the balloon or not, and nothing is known as to whether these shells burst in front or behind the balloon. Observation from the enemy's flank will tell this, but flank observation will not tell the truth about the accuracy of the line. Cross-observation is the only method by which it can be made an easy target, but as this type of artillery observing takes probably about twenty minutes, the balloon can be brought to the vicinity of the automobile or locomotive on the ground below, and thereby causing the enemy to take another observation, and just about the time that they are ready to fire a shot at the balloon, it is again moved, and thus plays a game of hide and seek with the enemy artillerists.

The most dangerous position of the kite balloon, is at the period of time when it is just leaving the earth, and until it arrives at a height of about twenty-four hundred feet. After once attaining this altitude, it is comparatively safe from attack from any source upon the ground. But this immunity is not perfect once an enemy air-plane arrives upon the scene of action.

At the base where the cable and the wires from the balloon reach the ground, are stationed twelve men, constantly sweeping the sky with powerful glasses. Enemy airplanes are sighted, an alarm is immediately sounded, the locomotive or locomotive winch begins to wind up the cable, which moors the balloon to the earth, and powerful anti-aircraft guns spurt out their fire at the balloons that are trying to swoop down upon their prey. The guns crash, nearer and nearer comes the balloon to the ground, the automobile or locomotive to which it is moored, starts to move, and gently draws the balloon to its nest, where it is concealed until another and better opportunity for attacking arrives.

The duty of the observers when they are up above the shell-torn lands "somewhere in France," along the American sectors, is to be ever watchful and detecting suspicious activities behind the enemy's lines, to take carefully note of the positions of guns, trenches and men, likewise to carefully check up reports of cavalry reconnaissance, to be watchful for the bringing up of reserves, and spot field works.
YOUR knowledge will always be the greatest factor in your success. No investment in the world will pay you bigger dividends than money invested in increasing your knowledge. And you can now do it in spare time, in your own home, for only 50c a week!

The pay-raising books described below were written by greatest authorities in their fields. Written in plain everyday language so anyone can understand and use the vast amount of knowledge contained in each set. Thousands of full page plates, photographs, diagrams, etc. Handsomely and durably bound in half Morocco or flexible bindings and stamped in gold. Select the set in line with your ambition, and examine it free. Mail coupon. If satisfied pay the Bargain Price, on terms of only 50c a week. Select your set NOW.

1.—Automobile Repairing
5 Volumes; 2500 Pages, 5½ x 8½ inches; 2169 Illustrations. Preparations for Garage Foreman, Automotive Machine or Chauffeur. Regular price $25. Special price $21.80. Terms, 50c a week.

2.—Law and Practice (with Reading Course)
13 Volumes; 6000 Pages, 7 x 10 inches; 24 Illustrations. Preparations for the Bar. Includes Bar Examinations. Regular price $72. Special price $39.80. Terms, 50c a week.

3.—Steam and Gas Engineering
7 Volumes; 3800 Pages, 5½ x 8½ inches; 2500 Illustrations. Preparations for Stationary, Marine or Locomotive Engineer or Fireman. Regular price $25. Special price $21.80. Terms, 50c a week.

4.—Civil Engineering
5 Volumes; 3000 Pages, 7 x 10 inches; 3000 Illustrations. Preparations for Civil Structural Engineer, Transitman, Estimator, Designer or Chief Draftsman. Regular price $25.00. Special price $20.80. Terms, 50c a week.

5.—Architecture, Carpentry and Building
10 Volumes; 4760 Pages, 7 x 10 inches; 4000 Illustrations. Preparations for Architect, Contractor, Construction Superintendent, Carpenter Foreman, Design or Chief Draftsman. Regular price $50.00. Special Price $41.86. Terms, 50c a week.

6.—Accountancy and Business Management
10 Volumes; 3680 Pages, 7 x 10 inches; 1957 Illustrations. Preparations for Certified Public Accountant, Auditor, Office Manager, Accountant, Credit Man or Bookkeeper. Regular price $56.60. Special price $41.80. Terms, 50c a week.

7.—Telephony and Telegraphy
4 Volumes; 1128 Pages, 7 x 10 inches; 2000 Illustrations. Preparations for Telephone Engineer, Wire Chief, Exchange Manager, Trouble Man, and Telegrapher. Regular price $26.00. Special price $12.80. Terms, 50c a week.

8.—Sanitary Heating and Ventilation Engineering
4 Volumes; 1164 Pages, 5½ x 8¼ inches. Preparations for Sanitary Engineer, Heating and Ventilating Engineer, Master Plumber or Plumber. Regular price $26.00. Special price $19.80. Terms, 50c a week.

9.—Mechanical and Architectural Drawing
4 Volumes; 1728 Pages, 7 x 10 inches; 1637 Illustrations. Preparations for Architectural or Mechanical Draftsman. Regular price $26.00. Special price $12.80. Terms, 50c a week.

10.—Fire Prevention and Insurance Engineering
4 Volumes; 1569 Pages, 7 x 10 inches; 900 Illustrations. Preparations for Counterman, Rate Clerk, Inspector or Agent. Regular price $26.00. Special price $15.80. Terms, 50c a week.

11.—Practical Bookkeeping
4 Volumes; 1848 Pages, 7 x 10 inches; 500 Illustrations. Preparations for Bookkeeper or Cost Clerk. Regular price $28.00. Special price $16.80. Terms, 50c a week.

12.—Modern Shop Practice
6 Volumes; 3000 Pages, 5½ x 8½ inches; 2500 Illustrations. Preparations for Machine Shop Superintendent or Foreman, Foundryman, Pattern Maker, Tool Designer or Tool Maker. Regular price $30.00. Special price $16.80. Terms, 50c a week.

13.—Electrical Engineering
7 Volumes; 3600 Pages, 7 x 10 inches; 2600 Illustrations. Preparations for electrical Engineer, Power Plant Superintendent, Substation Operator or Electrician. Regular price $35.00. Special price $15.80. Terms, 50c a week.

Not One Cent in Advance

Do not let doubt or delay deprive you of this opportunity to invest in your own self improvement. Mail the coupon today—right now—without sending a penny. You take no risk. If, after examination, you feel that spare time reading of these books will bring you a better, bigger paying job—if you are convinced that these books will pay you enormous dividends, send only the small payment each month, which amounts to less than 50c a week. You can better afford more than 50c a week with no return on your investment. Why not make that 50c work for you?

Mail Coupon Now

The increasing cost of paper and binding may force us to withdraw this offer when the present stock is exhausted. It is therefore important that those interested in mail the coupon at once and get the special price and easy terms. Mail the coupon and the books will come at once. Simply pay the small shipping charge, then return the set at our expense if you do not care to buy after examination. For a limited time, as a special inducement for prompt action, we offer with every set a Consulting Membership Free. This gives you the privilege of submitting your perplexing problems to a corps of experts for an entire year. This consulting membership ordinarily sells for $12.00. It is yours free if you act promptly. Mail the coupon before you turn this page. This offer may never appear here again.

A NEW "OIL SEALING PISTON RING"

This ring is made from a special formula of close-grained, tough graphite iron, a few points softer than the core of raw steel. Individually cast, retaining on the inside the skin of the casting, which insures long life and lasing performance.

A groove is cut around the ring at right angles with the face sloping at an angle of about 45 degrees, the groove passing between the side forming the lap and the side of the ring.

In one direction the square edge gathers the surplus oil. In the earring direction the oil is distributed again, from the sloping face, pulsating as it were, preventing the groove from clogging. Not only this, but today, when "gas is 20 per cent ker-}

it was found that the angular velocity of a flying machine moving with a uniform linear velocity, changes value every minute in practically all cases, and is expected that the angular velocity measured at the very moment of the shot could be applied to extrapolate for the point in the air which the projectile occupied, and this is questionable owing to the relatively long duration of the flight, any measurement taken at a moment somewhat prior to the firing of the shot is especially valuable and has no value whatever regarding the extrapolation desired.

This is the reason why, after the trials made with instruments capable of giving from time to time discontinuous measurements of angular velocities, it has been felt necessary to substitute instruments capable of giving continuous measurements, and this instrument is illustrated herewith. It is called a galvanometric cinemometer.

The instrument works on an ingenious electrical principle as follows: A steel armature, turning in a solenoid (coil of wire) develops a current of induction, the intensity of which is a measure of the velocity of rotation. If the steel armature is set in motion, a sighting telescope pointed at the airplane, a galvanometer properly graduated will enable the range-finding officer to read constantly and independently the linear velocity of the moving target. As the illustration of the measuring instrument shows, there are two steel angles and two solenoids provided; one measures the angular velocity when the telescope is moved across the horizon, the other solenoid and armature indicating the angular velocity when the telescope is moved up or down vertically. A mean value is obtained from both instruments when the telescope is moved diagonally or up and sideways, for instance. The problem of aiming and firing an anti-aircraft gun is thus a considerable one, and moreover highly scientific in its solution, for among other things, the officers having to do with the range-finding, have to determine the altitude or height of the enemy plane, its direction and its velocity, either angular or linear; the extrapolation or prediction of the point to be aimed at, from where the knowledge of the azimuths is determined is then measured by triangulation from a large observation base. In all these calculations and estimations, and particularly suggested, the use of the well-known plotting board, familiar to all artillersists, is recommended.

In determining the azimuth when the angular velocity of the target is determined by the aid of the instrument here shown, the extrapolated azimuth is obtained by the plotting of the horizontal angular velocity and this is in starting from the last azimuth in which the target has been observed, prior to the firing of the shell, the angle of sight is extrapolated or plotted from the angular velocity taken in the plane of sight where the target has been observed. prior to the firing of the shell.

Consider once more the fact, as aforementioned, that an enemy aircraft may traverse a distance of about seven hundred meters or 434 mile during the flight of the projectile thru the air. The shell proceeds on its way and clings helplessly to its trajectory, and if the case be so, the combustion of its fuse has come to an end. In the words of Colonel Reille—"During this period the race is surely most important, for it is during this time that the guidance of a quick-witted aviator, has maintained the full power of her free will,
LEARN PUBLIC SPEAKING

10 Lessons FREE

Write—quick—for particulars of this extraordinary offer; an opportunity you will never forget if you take advantage of it. Ten lessons in effective public speaking absolutely FREE to those who act promptly, to introduce our course in localities where it is not already known.

WHAT THE COURSE TEACHES YOU

How to talk before your club or lodge.
How to address board meeting.
How to propose and respond to toasts.
How to make a political speech.
How to tell entertaining stories.
How to make after-dinner speeches.
How to converse interestingly.
How to write better letters.
How to sell more goods.
How to train your memory.
How to enlarge your vocabulary.
How to develop self-confidence.
How to acquire a winning personality.
How to strengthen your will power and ambition.
How to become a clear, accurate thinker.
How to develop your power of concentration.
How to be the master of any situation.

We Teach You By Mail

We teach you by mail to become a powerful and convincing speaker—to influence and dominate the decisions of one man or an audience of a thousand. We have trained hundreds and helped them to increase their earnings and their popularity. Learn in your spare time at home how to overcome “stage fright” and conquer fear of others; how to enlarge your vocabulary; how to develop self-confidence and the qualities of leadership; how to RULE others by the power of your speech alone; how to train your memory. Our

NEW, EASY METHOD

perfected and taught only by Prof. R. E. Pattison Kline, former dean of the Public Speaking Department of the Columbia College of Expression, can be learned in 15 minutes a day. Prof. Kline is one of the foremost authorities in the country on public speaking and mental development. Do not let this chance escape you.

Mail This Free Coupon

This Special Offer of TEN LESSONS FREE is made strictly for advertising purposes and will be withdrawn without notice. Write now, before it expires, and receive full particulars with enrollment blank by return mail. No obligations of any kind. Just tear off and mail this free coupon—or a postal will do.

You benefit by mentioning the “Electrical Experimenter” when writing to advertisers.
WHY AIRPLANES DON'T FEAR ANTI-AIRCRAFT GUNS.

(Continued from page 494)

AERIAL PROJECTILE FROM THE GROUND BURST ANYWHERE NEAR THE 'PLANES, AND AT ONCE SHE IS IN A POSITION TO THOROUGHLY BATTLE ALL THE CALCULATIONS THAT HAVE BEEN WASTED ON THE AIMING AND FIRING OF THIS PROJECTILE. DUE TO THE CORRESPONDING FACTS, IT IS CLEARLY EVIDENT THAT THE SYSTEMS OF ANTI-AIRCRAFT FIRING BASED SOLELY ON RANGE MUST BE CONSIDERED AS BEING INEFFECTIVE AND EXCESSIVELY EXPENSIVE.

"Also," as this authority, who is Chief of Artillery in the French Advisory Mission concludes—"are they not sufficient to show that, so long as we do not have a gun of a fantastic muzzle velocity, and capable of pouring into space projectiles of a speed infinitely superior to that of the flyer itself, that any gunner must concentrate all his attention and ingenuity in throwing skyward, sudden and dense barrages on the points in the air determined by extrapolation, silently calculated by measurements as accurate as possible."

A THERMOSTATIC TIME SWITCH.

(Continued from page 475)

This device will afford considerable amusement to many people unused to the ignition by those who see the lights flash on apparently by themselves, as the operator has ample time to move away from the push-button before the lights light.

The Electric Safety razor makes shaving a pleasure. Blade takes innumerable shaves before it cuts the beard smoothly and without slightest pull or irritation—feels like a gentle massage. Can be used with or without electric current.

All sorts of the Lek-Tro-Shav speak well of it.

A barber says—"Have shared for years and have never owned or supplied a razor before. A house wife says—"The most pleasing shave I've ever had. Simple, easy to use and need not be shared, but there is no after irritation of any effects as I usually get from a razor.

A man writes: "Please send me a 'Lek-Tro-Shav' Basket.

No. 2 Made for use by lady.

Write for illustrated circular describing Lek-Tro-Shav Safety Razor fully.

and place them in the mine. In another compartment of the mine place a ton or so of gun-cotton or T. N. T. "Now," sez he, "when all is ready, and the compasses duly fitted with an electrical contact, it will swing around and close the spark coil circuit, thus detonating the high explosive as soon as a steel ship draws near; but how in blazes am I going to tell enemy ships from my own?! I should worry!"

GADZOOKS!!! Lads, but look at war dream No. 4! What do our eyes behold, my Lords? Nothing less than the evil eye and titanic grin of the terrible Electro-magnetic torpedo! Why should mighty torpedoes be wasted by missing the mark, when such an invisible and omnipotent force as that of magnetism is available, writes this "also-ran" inventor. No sooner said than done, and down he sat and penned this drawing and specification. I would assure you friends that if I were as big as the biggest torpedo, with a girth of twenty feet and a length of ten yards, and just bubbling over with magnetic molecules, I would not be unable to do any job, which you ever saw at a distance exceeding a few inches at most. If you do not believe it, just go down to the nearest steel foundry where they have an electro-magnetic capable of lifting several tons, and see for yourself how far my magnetic influence extends.

The "electrification" experts had been at it again when I ran across Phoney Patent No. 5. "Take some ten thousand of your electrical experts" sed this inventor in his specification, "and let them in their most industry and address to no less a personage than General Pershing himself—send them down to the sunny shores of the Meditteranean, and let them improve each shining hour by gathering thousands of No. 1 electric eels. Ship said eels to the Western Front in plate-glass trunks, so that they cannot break while in transit, and note at the psychological moment, liberate fifty thousand for luck from airplanes flying along the Rhine into that German holy of holies, and the war will be ended." I commission that budding genius with the rank—I sure think it's rank—Brigadier-General of the Electric Eel Division, and he can have full charge of that Department any time he wants it!

I momentarily lost my equilibrium and nearly fell to hold my magnetic molecules in line, while old "H. P." nearly fainted, when my gaze fell on the Patents No. 6. CARABBA!!! What do you think of this magnificence? I say, a chap that promulgated and otherwise foisted this brainy (?) idea on a long-suffering War Board was a Colonel— Colonel, my good friend. Patented it, he wrote—"Why not build a VERY POWERFUL ELECTRO-MAGNET and submerge it in the shal low waters about the North Sea, so that the enemy battleships will be attracted from the deep channels into the shoals, where our sea forces can knock them to smithereens." Well, boys, I am all for this scheme for myself; I'd take a tip from father, that if that bird could build an iron core large enough for me to slip around it with my body, a couple of copper wire, big enough to use all the kilowatts developed in Europe, well then I could not cause any of the mighty steam battleships of the British Navy to move one-thousandth of a millionth part of an inch from their chosen path. Of course, if a noisy submarine tried to interpose itself, I might get a few 'em, but with the help I provided I had several thousand kilowatts of magnetized molecules tuned up to a state of shock to hold him in his place. But none of that five-mile or ten-mile stuff, or quarter mile either.

I have often wondered how it would feel to have several million of my body's transferred molecules concentrated on the nose of a
WIRELESS

Prepare while you can for this branch of government service in which there is exceptional opportunity for better pay and rapid promotion. Our courses qualify men 18 to 45 as expert Wireless Operators.

Aero Division

There are thousands of responsible positions open to competent wireless operators. Our land, sea, and air forces, as well as the great merchant marine, need specially trained men to act as operators, electricians, engineers, and inspectors.

Our Wireless Course prepares you in a short time to qualify for a Government license. The course is most complete, covering all make and kinds apparatus. Our competent instructors and individual attention insure rapid progress.

This branch of the service applies to live wires, offers great opportunities for advancement.

Electrical Arc Welding

Our intensive two month's course prepares for positions in Gov't ship-yards, paying $2,400 per year.

ELECTRICAL EXPERIMENTER

November, 1918

fast-traveling bullet, so that when approaching the steel helmets of the Kaiser's finest, they would immediately yank the bullet out of its wonted course, and cause it to slam mightily against Fritz's steel sky-piece, and by this sudden concussion cause the bullet to spurt into the air. You can imagine the results.

A budding genius from Whitewater, H. R., propels the Naval engineers shall equip all sea-going vessels with a series of (always) "large and powerful" magnetic coils, placed in belt lines entirely around the hull of the ship, and exerting magnetizing coils with several hundred kilowatts of alternating current. Now, aloha you might not know it, when an alternating current is past through an iron mass, I can repel certain bodies with extreme speed, but not for any great distance, usually not exceeding a few inches. You can imagine then what chance I would have of repelling a modern automobile thunderbolt traveling at the rate of fifty miles an hour, and with a momentum of many thousand foot-pounds.

Boys, Howdy! Take off your hat to war, spasm No. 9, specially invented to hasten peace, so to speak, to make my bones weary, for I'll be dinged if he doesn't pack up a bunch of my best trained Maxwellian molecules into an iron lifting magnet and meagre me in a thousand feet in diameter, and whirl it along until the molecules suspended from an airplane. You must hear that boy rave. I can see the boche on a dead run for Berlin, can't you? Yes, you can't! Not the Sun was such a pleasant smile in Fig. 9—it must be a warm day in July—lie right is right!

How Can We Tell "Real" Death?

(Continued from page 457)

which is usually injected into the jugular vein in the neck after the blood is withdrawn, is composed of a certain chemical solution which tends to prevent rapid decay of the tissue. When the body is embalmed, it is impossible for a person to come to life again (as far as we know) from a state of suspended animation). So it becomes all the more important to know an exact test for determining absolutely cases to exist, even before embalming as becomes obvious.

USUAL TESTS FOR CESSION OF LIFE

1. Pulse and Heart Beat: The pulse, as the pulse of life, appalls we, and this is felt by grasping the wrist so that the heart and inferior border of the rib are compressed against the heart, and this definite pulse is felt. As the life approaches the end, the heart rate decreases and may decrease to 10 per minute. It is usual for the physician to listen to the heart beat with the stethoscope. There is also available what is known as the microphone stethoscope, which is supposed to be extra sensitive, for the better appreciation of the slightest heart beat. Some physicians, however, state that the most sensitive method of listening to the heart beat is to rest the ear against the breast, upon which a piece of gauze has been placed for chilling reasons and which does not interfere with the transmission of sound from the heart to the ear. The stethoscope in such cases is liable to amplify or localize other sounds, such as the movement of the breasts, which tend to movements of the heart in the lungs, or due to congestion in the lung passages, especially where the patient has been affected with what is known as death rattle. If the heart has to all appearances and purposes ceased to beat at the breast over a period of five minutes and then for another period of five minutes is alive, to assume that the patient is actually dead, for in practically all ordinary cases of suspended animation, the persons so affected have come to life after a period not exceeding three minutes. Finally, the radial artery may be opened at the wrist. If blood flows when pressure is made, it indicates that the heart is still alive, and the patient therefore not actually dead. In the case of suspended animation, it is the opinion among medical men that the pulse is not really departure from the body, and no authentic case is on record where such a condition has occurred, as Dr. John B. Hulber has pointed out.

2. The Respiration Test: Respiration normally occurs at the rate of sixteen to eighteen per minute, but this may drop to as low as three or four per minute as life approaches its finality. An old fashioned test which is a fairly good one and extensively used at the present time is that of putting the hand upon the breast of the mouth. In the case of syncope, any slight action of the muscles may cause the breath, which forms a mist on the mirror, This test, however, may be put to the advantage of the physician in cases of severe shock, as any movement of the breath provides an indication of life. The only ordinary test will indicate this condition by stopping the action of the breath at the wrist.

Even the slightest breathing can be heard by the ear applied to the breast, especially by the trained ear of the experienced physician. The death rattle is one phase of it, and finally rises with water.

3. Body Temperature: When life ceases to exist the temperature of the human body invariably drops rapidly, or at the rate of approximately 1.6 degrees Fahrenheit per hour. The living body has a temperature of 98.6 degrees, but may die down to 58 degrees, and have a temperature as high as 106 to 108 degrees. The living body temperature is, however, not constant, but varies degrees temporarily, in some serious cases of cholera or yellow fever, about 95 degrees is usually considered the minimum temperature at which life can exist. Sometimes the temperature will rise above 100 degrees both before and after death, but this is purely a chemical reaction in the different parts of the body. The body is at a higher cooling, and room temperature may fall in from three to twenty hours after death of the body has been noted after a period of as long as three years.

4. Color of Skin: To all intents and purposes, if the skin has been freshly dead and has practically ceased, the skin of the body becomes deathly white, and there is absence of the pink color when examined. The tissues of the body lose their elasticity, and finally the body becomes in a state of rigor mortis.

Skin Signs: Scarification of the skin and use of a cupping glass fails to draw blood. Injection of the skin with a fluid, as a rule, followed only in life by a port wine colored congealed blood, and finally myoglobin when approached toward a light if there is circulating blood.

EXPERIMENTAL CHEMISTRY.

(Continued from page 491)

the right angle bend, is connected to a medium size test tube, which is immersed in a vessel filled with water. Pour in 5 or 6 drops of sulfuric acid thru the thistle tube, and again place the vessel in the water. If the vessel is a small amount of antimony sulfide, or other substance, the tube will be seen to be filled with water. A drop of the fluid is placed on a piece of glass, and the dish is observed for the presence of any distinct color. In the case of antimony sulfide, a greenish color appears. In the case of antimony trichloride, a yellow color appears.
In Which Line Will You Do Your Bit

YOU have got to do your bit in the big task facing America. How will you do it? Will you be able to sell your services at big pay as a skilled worker, or will you have to put in your time in unconfident work and get little for it BECAUSE YOU LACK TRAINING? America is faced with the problem of finding men who can think and act for themselves. It is a big problem. Trained men were never scarcer, and yet think what this scarcity will be like when America jumps into the work of reconstruction. Skilled workers in every trade and profession will be at a premium. There will be work for you, for every man, for years to come. The choice of what you do and how much you earn is up to you. What are you going to do?

Prepare NOW Profit Later!

The fact that trained men are the money makers, that they are always in big demand, that their training is insurance against lack of employment, should make any man see the wisdom of training. You can't get anywhere without it—but you can go a long way with it. You have to work for a living. Why not get the most for your efforts?

Begin to prepare now and it is but a matter of months before you are capable of earning more money—a year or two before you are master of the job you want to hold and making the money you want to make. Training calls for no great sacrifice. Just devote one or two hours a day—time you now waste—and your study will well repay you. Systematic home study will make it easy for you to master any of the Courses below. Nor is the cost of such training out of your reach, no matter how little you may be earning.

At our risk—Take 10 Lessons at OUR Expense!

Begin your training with the first lesson of the Course you select. If after ten days you are not satisfied, simply notify us and the Course will be yours at no cost. At our risk we offer you the Satisfaction of our guarantee.

Training Decides Your Pay

There is no sentiment in determining your salary. You get paid for what you do. What you do depends on what you know. The difference between $15 a week and $50 is the result of training—knowing HOW. Training alone gives you the power to satisfy your ambition. The way is clear for you to acquire a good, practical training without interfering with your present work. Check and mail the coupon below. We will promptly send you Free Bulletin of the Course you are interested in, and full details of our methods, easy payments and guarantee. Send TODAY.

PATENT ADVICE

Edited by H. GERNSBACK

In this Department we publish whatever as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Regular inquiries addressed to "Patent Advice" cannot be answered by mail free of charge. Such inquiries are published here for the benefit of all readers. If the idea is thought to be of importance, we make it a rule not to divulge details, in order to protect the inventor as far as it is possible to do so.

Should advice be desired by mail a nominal charge of $1.00 is made for each question. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

Readers' attention is called to the fact that due to the great amount of letters to this department it is quite impossible to answer them all thru these columns. The inquiries answered in this issue date as far back as May, and if readers with speedy service they should carefully note the announcement appearing in the preceding paragraph.

Spring Handle.

(270) Fred A. Shearer, Centralia, Wash., has an idea to prevent handles attached to tool chests, etc., from being broken in transit. They are often broken when thrown off trains. His idea is to place a small wire spring in the handle to keep it closed, thus preventing damage. Our advice is asked.

A. Spring handles are not new, and there have been a great many styles on the market. Any first class hardware store carries such handles.

Stereoscopic X-Ray.

(271) Robert J. McGill, Washington, D. C., submits a plan of X-ray work for quickly locating a foreign object in a body. He has two simple shadows upon fluorescent screens which are at right angles to each other and at a stereoscopic angle to each other, so that the observer, (see illustration) can get an idea of the depth of the object as well as the location laterally. By using a stereoscope, the observer may combine the two views so as to give the appearance of solidity to the subject, and the operator in the "mind's eye." This principle may be used for observation and diagnosis of cases other than those where foreign bodies are located in the patient's body. Our advice is asked.

A. This seems to be a particularly clever idea, and also stereoscopic X-ray pictures have been taken before, we do not think that we have come across a scheme whereby the object can be seen stereoscopically direct by means of a fluorescent. Hereafter pictures were taken on regular photographic plates, and these pictures were then in turn viewed by means of a stereoscope. We think this idea is patentable but as a precautionary measure, we would ask our correspondent to get in touch with a patent attorney to have him make a search.

Sub-Aquatic Wireless.

(272) H. K. Skinner, Oxford, Ohio, wishes to know if he could get a patent on underground wireless by applying same to a submarine. Our advice is asked.

A. The sketch which our correspondent submits outlines the idea, but he evidently forgets that salt water being a fairly good conductor will transmit wireless waves from being propagated under water for any appreciable distance. For this reason the idea can hardly be called practical.

Double Caliper.

(273) Lawrence Byrne, La Salle, III., submits a double caliper as shown by attached diagram. As will be noted points A A are used for calipersing the inside, and points B B are used for measuring the outside of the work. Our advice is asked.

A. This is a particularly clever idea, and we are quite certain that a patent can be obtained upon it. We do not think a caliper of this sort exists at the present time. We advise our correspondent to get in touch with a patent attorney.

Miscellaneous Patent Questions.

(274) M. A. Levin, Pueblo, Colo., submits several ideas. We answer them as follows:

1. The use of selenium in connection with measuring the candle power of various light courses is not new, having been often described in text books. The idea of having a swinging record on a moving picture film, so as to make so-called speaking pictures in not new. This idea was described a long while back by us and is the so-called Hartmann process. It is patented.

3. The use of selenium as resistance in connection with moving pictures is not practical as outlined by our correspondent.

Aerial Torpedo.

(275) H. Reichart, Edmonton, Alta., Can., has invented an aerial torpedo propelled by the escaping gases, on the principle of the sky rocket, with a small explosive charge in the war head. The torpedo is supposed to be used from aeroplanes.
only, and weighs a few pounds, but is destructive enough to damage an enemy plane or dirigible balloon. The torpedo could be started from a sort of small motor which would ignite the powder and propel it until it was traveling under its own power. The distance it would travel could not be far and a small angle for firing would be necessary, it probably would have a destructive effect.

A. An idea of this kind, while it is good and while it makes practical sense, has the great drawback that, like all other devices to combat airplanes, it will be ineffective, for the reason that airplanes travel too fast, and even if it were possible to make the flying machine self-propelling and self-steering, how could it overtake an airplane manned with a thinking pilot who changes his course at will. A mechanical device, of course, could do nothing of the sort, as you could not make it follow an airplane. Mechanisms of this kind, while interesting, are not very practical, even if they should be controlled by wireless.

CODE PRACTISE INSTRUMENT

(276) A. E. Kopp, New Middletown, Ind., sends in a drawing and description of a code prac-
tise set, and the illustration which we reproduce below shows it is practically self-explanatory. As will be noted the bulb D is mounted on the cross piece, while the key C makes contact with the bottom of the bulb thru battery B. It will, therefore, flash every time the current is made. A. This is a very clever idea, but there is one thing we do not like about it, and that is the current is broken on the downward stroke. As a rule such outfits are not liked very much, and if our correspondent could devise an instrument where-by the current is made on the downward stroke, we believe he would have a much better apparatus. However, even in its present state we believe a patent can be obtained.

Expansion Toggle.

(277) D. W. Booth, Montreal, Que., Can., submits an idea on an Expansion Toggle which illustrate. Our advice is asked as to patentability and practicality of the design.

Novel Form of Expansion Toggle Proposed

By Inventor

(278) Paul B. Kingley, Cheyenne Wells, Colo., submits the following: "Just recently I purchased a bottle of Le Page's glue. After removing the metal body and screw cap, I was immediately confronted with the problem: How shall I remove the cork? I finally succeeded in prying the cork out with a knife, and sat down and thought. An idea came to me. I secured a screw of the rounded-headed variety, and...

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
after punching a hole thru the metal cap I thrust it thru and turned it into the cork. Then I could remove the cork easily and re-place the two when operation. See illustration. Why not make corks along similar lines, to be used on such bottles as Manufacturing Varieties. Various modifications of this idea may be made from a mechanical standpoint. Particularly keep the screw (or swivel pin) from pulling out the cork. Would fly your opinion on this subject? A. While the idea is clever and no doubt practicable, we are often in a hurry to once opened—no need for cork. When in use they are at no time in my possession being kept in the bottle, and for that reason the metal cap as a rule is used, which presenting little surface does not stick as strongly as the large cork would. Opinion is that from a practical standpoint, an invention of this kind would not be very satisfactory.

THE DUNWOODY INSTITUTE.

The William Hood Dunwoody Industrial Institute, at the endowment of five and one-half million dollars "for training in industrial and mechanical arts," is now training a large number of men under contract with the government for both Army and Navy. One of the interesting departments in connection with this training is the Radio Department, in which are under training over 200 Navy radio students and fifty Army radio students.

The men are in the Navy or indented into the Army or Navy are sent to the Institute for an eight to ten weeks' course of instruction in both operating and theory. The Institute has shown an increase in the quota of radio students under training and needs additional instructors for class work in theory and laboratory operating. Any men having proper qualifications, if interested, should write to The Dunwoody Institute, Minneapolis, Minn., for further particulars.

HOLDING DEATH

(Continued from page 498)

Muscle Signs: In death the muscles show an ACID in lieu of an ALKALINE reaction during life. Nerves throw into action muscles become oxidized. A living muscle responds by contraction to a factor which is applied to it. The response diminishes after death and is lost in 3 hours. If 20 minutes have elapsed after presumable death and the muscular contractility is unaltered—the subject is NOT dead. (electro-histo) A woman who lay for 32 hours deprived of apparent vitality was saved from burial.

Icaria's Fluorescent Sign: This is probably one of the most interesting signs of death, reliable, and the drug is innocuous. A solution of 15 drops of Fluorescein, 15 grains of Sodium carbonate and 120 grains of water is injected under the skin. As long as the eye does not close, the injected fluid spreads rapidly, and in this case the sign is effective within 2 or 3 minutes. The eyes simultaneously become emerald green. With a slow circulation its coloration may continue 2 or 3 minutes. NO COLORATION shows that life is extinct.

Eyeball Signs: In death the eyes are invariably open, but they may appear to be closed for the reason that the upper and lower lids both droop, the upper lid drooping about half way over the pupil and the lower lid as high as the papilla; the sipping of the lower lid causes the white of the eye to be noticed and hence it is generally thought that the eyeballs are pointed upward, but invariably point straight ahead. Closed by skillful manipulation on the part of the undertaker. In real death the eyeballs lose their extreme tenacity which in cases of syncope or suspended animation. A flash-light thrown in the eye may reflect this test known as the light test.

The central test is made by scratching the cornea of the eyeball with the finger nail — in real death no movement of the eyeball or reflex should occur. With regards to the face, the mouth involuntary closure and reflex should be noted. This must be closed by the undertaker, preferably before the body has become cold and the muscles set.

6. Rigidity: The arched muscles of the limbs and the rest of the body do not always indicate real death, and that in this condition can also occur in cases of syncope or suspended animation. A flash-light passed through the eye, or reflected from the test being known as the light test.

NEW AND PROPOSED TESTS FOR CESSATION OF LIFE

1. The Litmus Paper Test: As is well known, litmus paper changes color upon whether a solution or secretion is alkaline or acid, the paper changing color accordingly. In applying this test for the purpose in question, a small piece of paper is employed, one end of which is placed

The Dunwoody Institute's Radio Department is training over 200 Navy radio students and fifty Army radio students. Any men interested in pursuing a career in radio technology, if they have proper qualifications, are encouraged to write to The Dunwoody Institute for further details.

Icaria's Fluorescent Sign is another method of detecting death. A solution of 15 drops of Fluorescein, 15 grains of Sodium carbonate and 120 grains of water is injected under the skin. The eyes simultaneously become emerald green. This is a reliable sign if the eye remains open and able to respond to light.

In real death, the eyes lose their extreme tenacity and may not respond to manipulation by an undertaker. However, in cases of syncope or suspended animation, the eyes may still show movement.

The Central Test involves scratching the cornea of the eyeball with the finger nail. In real death, no movement of the eyeball or reflex should occur. This test should be performed by the undertaker, preferably before the body has become cold and the muscles set.

The Litmus Paper Test is another method for detecting cessation of life. A small piece of litmus paper is placed near the body, and its color change can indicate whether the body is still alive or not.

In summary, the Dunwoody Institute is providing valuable training for men interested in the field of radio technology, and various methods are being used to detect death accurately.
on the eyeball or on the under side of the lid, and if it does not change color it may indicate a syncope condition. This is the reason: In the skin and eyelid exudations are alkaline, while when death occurs bodily decomposition and its various chemical reactions set in, therefore these exudations become acid. Hence we obtain the acid reaction on the limbus paper in this test, if the person is really dead. This is one of the best and newest tests available, says Dr. Sinclair Tousay. A simple method of obtaining a solution (ether or chloroform), a few drops of which are placed on the eyeball, and the solution, due to the actions just mentioned, will cause the eyeball to turn red and slightly swell, if life still exists in the body, even though all other tests indicate differently. If no coloration or movement of the eyeball occurs, then death can be considered to have taken place, says Dr. Albert C. Sums.

2. The Electrocardiograph Test (proposed by the writer): The writer has employed the very minute electric currents produced by the pulsations of the human heart, as explained in an article on the Electrocardiograph which appeared in the May 1917, issue of this Journal, it would seem that by applying the electrocardiograph to sensitive Einchoven arcing galvanometer or an equally sensitive instrument to the body, then the slightest changes in the heart would produce a measurable electric current, which would register on the photographic recorder of the apparatus. It would also seem possible for every place in the body to be equipped with a special portable instrument of this type for the purpose in question.

3. X-Ray Test (proposed by Mr. H. Gernback): Suggested on the strength of the fact that with the improved high-power X-ray apparatus available today various parts of the body can be photographed, including lungs, which owing to the absence of air in the diseased lung, photograph black.

4. Abrams' Test: This is based on the fact that a beating heart produces radioactivity and yields a characteristic reflection. As long as the heart beats, this reflection can be elicited. A detailed description of this test is given in the technical for the average layman.

5. Weighing the "Soul": This is probably a rather far-fetched and mythical proposition, but according to reports current some time ago, it was claimed that tests were made with a specially sensitive balance, on which a glass of water was placed and later died. The physicians claim that after making every conceivable precaution for bodily decomposition, both organic and gaseous, there was still a discrepancy of about four and one-half ounces, higher than all other methods could account for in the case of Mr. F. Bach, and they attributed it to the soul departing from the body.

We print this statement for what it is worth.—Editor.

Conclusion: "The danger of premature burial has no longer been exaggerated, for the diagnosis of death by a competent physician should be made obligatory by civil law," says Mr. Abrams, the well-known medical authority. "A period that may elapse before burial should be fixed by law. In France, it is 24 hours; in Germany, 48 hours; and in England, it is customary to await putrefaction, which in such countries of Greece and Rome, where 6 to 11 days were allowed between death and the funeral."

WESTINGHOUSE ENGINEERS GET NEW RESEARCH LABORATORY. (Continued from page 459)

materials laboratory, the ceramic laboratory and the research laboratory. The latter is housed in what is known as "the new research building." The growing demands for more fundamental work made it desirable to provide a special building where advanced science and research problems could be better separated from the more insistently problems. A location about a mile distance from the works was selected, partly on account of the excellent condition in the vicinity of the works, but more especially to secure a site relatively free from vibration and noise which would afford a certain amount of isolation.

The power house contains motor-genera
tor sets for supplying single-phase, two-phase and three-phase current at 220 volts, and direct current at 250 volts (three-wire circuit). A motor-driven air compressor supplies compressed air at 265 lb. pressure, and a large motor-driven vacuum pump supplies the necessary house vacuum. A liquid air machine capable of supplying 1½ to 2 liters of liquid air a minute is also installed in the main power house. The storage battery is in a separate room in the basement of the power house and consists of a total of 218 cells, so divided that various groupings and combinations may be obtained.

Shipped Postpaid for Seven Days' Examination

Just send us a money order or check for $3.75 attached to the coupon below, and a copy of Practical Aviation, no. 42, will be mailed to you. Examine it carefully—read it—see it for seven full days. If at the end of that time you feel the book is not suited to your needs, send it back to us and we will refund your money.

This offer is open to every man within the boundaries of the United States and Canada. Fill in and mail the coupon now and secure a copy of the very latest and most up-to-date book on the important subject of aviation.

American Technical Society, Dept. EE 11-18, Chicago, U. S. A.
Learn Aviation Mechanics

Train yourself for the Aviation Service by availing yourself of the Preparatory Ground Course in Aviation Mechanics, affording preparation prior to entering Government Ground School, covering auto-dynamics, aero-engineering, flying and Lewis gunnery. Previous experience unnecessary.

COMPLETE COURSE (engine course), taken in six weeks (three hours daily) or three weeks (six hours daily)........ $60

Special Aero-Engine Course (three weeks)........ $35

Wireless Course (four weeks)........ $25

Day and Night Classes Begin Every Monday

A WATER-JET BLAST APPARATUS

(Continued from page 476)

the water outlet, it should be stopped by tightening the water outlet pinch-cock. By regulating both pinch cocks a place is reached where the water reaches a constant level, all air going out to the air delivery tube, and all water going out the water outlet tube.

An apparatus such as just described was made by the writer and has been in constant use in his laboratory. It supplies sufficient air for two blast lamps, and will give at least five pounds of air pressure for injection purposes, etc. If more air is needed then three injectors may be used, or if not as much is required, only one injector is necessary.

If a combination blast and vacuum apparatus is wanted then one, or both of the injectors may be made into a water-jet vacuum pump by the addition of a "F" fused on to the air inlet hole. If both are thus equipped, a blast and suction cannot be obtained at the same time unless one air opening is left free. One injector may be left open for the air supply and the other used for suction. But in doing this the supply of air is cut in half. Usually there fore it is better to leave both air inlets open and make a vacuum pump separately, then both may be used at the same time without loss of air.

In this way, and with a minimum of expense, and with a very little knowledge of glass blowing, an efficient suction and airblast apparatus run by water pressure may be constructed so that they will be in every way as satisfactory as the factory-made product.

ELECTRICITY AIDS HUN MOVIES

(Continued from page 455)

The final episode of this series is brought to a dramatic climax by showing the final efforts of the Kaiser’s spies to weaken their hatred on America up to the very moment war was declared.

Harrison Grant and Dixie Mason know that Ambassador von Bernstorff will not leave the country without making a supreme effort to cause damage to American resources. Ceaseless vigilance directs their
TALKING THRU LAND AND WATER.

In Fig. 1, as the operator speaks, changes in the microphone resistance will occur, corresponding to the fluctuations of the voice. These variations will cause differences of battery current to reach the electro-magnetic oscillator, which in turn will radiate powerful sonic vibrations or sound waves corresponding to the spoken voice. These electric sound waves transmitted thru the earth or water, are picked up by a microphone (or by a receiver and antenna) and caused to affect the telephone receiver in the same way as the telegraphic dot-and-dash signals do. The recorded sound signals have been transmitted to a distance of twenty miles by this method, and telephonic speech has been transmitted and received over distances of more than ten miles.

One of the most interesting phases of this recently patented invention (U. S. Pat. 1,270,998) is that by means of a compound microphone arrangement (mounted in one of these liquid tanks or ground pits so as to be revolved thru any desired angle) it becomes possible to very accurately determine to the fraction of a degree, from just what direction a sound wave is propagated! A combination of this principle in the new Fessenden sound-transmitting and receiving apparatus, is shown in Fig. 3, where, by means of two oblong tanks arranged with the special "sound direction detecting apparatus," it is possible to quickly and accurately locate any activities on the part of enemy "sappers," who may be engaged in digging a mine.

The principal feature of the whole arrangement here outlined, is that the signal-producing or receiving instrument is not in direct contact with the earth, and does not vibrate with the same phase or amplitude as the ground itself. Hence the transmitting or receiving point, thereby avoiding losses from refraction, bending, or irregular travel of the sound waves, and enabling the true direction of the sound to be rapidly ascertained, and permitting amplification by mechanical resonance, etcetera; as will become evident.

Referring to Fig. 3 and the detail illustrations, the right showing a close-up view of one of these "sound direction" detectors, we see that a large pail-shaped tank of water is sunk in the ground to start with. The ground around the pail is preferably wetted so as to make good physical contact between the pail and the ground. A three-legged metal spider rests at the bottom of the pail, and this is surrounded by a sound-insulating pedestal made of lead. In this sound-insulator is placed a vertical and revolving metallic rod which carries a pivoted cross-arm supporting a sensitive microphone.

(Continued on page 507)
DO YOU KNOW?

Do you know how to make chemical tricks?
Do you know how cloth is bleached?
Do you know how to test soil?
Do you want to make invisible ink?
Do you know how to test flour?
Do you know how Chlorine Smoke and Chlorine Gas (German War Gas), is made?

What do you know about chemistry in general?

These and hundred other interesting questions are answered and demonstrated with our Chemistry Laboratory which we present here with.

The chemicals furnished are all technically pure and put up in appropriate wooden boxes and glass bottles, and there is a sufficient quantity to make dozens of experiments with each. The apparata are of standard laboratory size and quality.

Altho all chemicals have nearly doubled in price, we have decided not to raise the price for this outfit for the present.

Read the list of chemicals and apparata and look at the actual photograph of the outfit at your right.

And order one today!

THE E. I. CO. CHEMICAL LABORATORY

DESCRIPTION OF THE OUTFIT

It contains the following 44 chemicals:

- Ammonium Chloride
- Alum
- Antimony
- Boracic Acid
- Charcoal
- Sodium Nitrate
- Sodium Carbonate
- Sodium Borate
- Sodium Sulphite
- Manganese Dioxide
- Oxalic Acid
- Brimstone
- Iron Oxide
- Sulphate of Zinc
- Magnesia Carbonate
- Zinc, Metallic
- Sodium Bicarbonate
- Sodium Sulphate
- Sodium Chloride
- Calcium Sulphate
- Barium Chloride
- Lead Acetate
- Ferrous Sulphate
- Nickel Sulphate
- Sodium Phosphide
- Zinc Carbonate
- Ammonium Sulphate
- Ammonium Carbonate
- Ammonium Aqua
- Calcium Chloride
- Chloride of Zinc
- Copper Sulphate
- Glycerol
- Iron Chloride
- Calcium Oxide
- Stannous Chloride
- Nickel Chloride
- Hydrochloric Acid
- Sulphuric Acid
- Iodine
- Mercury, Metallic
- Tin, Metallic
- Litmus Paper
- Ferrous Sulphide

The following apparata are furnished:

- One Standard Washbottle
- One Conical Glass Measure
- One Erlenmeyer Flask
- One Glass Funnel
- One Delivery Tube
- Six Assorted Test-Tubes
- One Test-Tube Holder
- Ten Sheets of Filter Paper
- One Glass Dropper
- One Spoon Measure
- Glass Tubing

We present herewith to our friends our new E. I. Co. Chemical Laboratory which contains real chemicals and apparata to perform real chemical experiments. This outfit is not a toy, put up merely to amuse, but a practical laboratory set, with all the chemicals, apparata and reagents necessary to perform real work and to teach the beginner all the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

44 Chemicals
17 Apparata
1 Instruction Book with 100 Experiments

PRICE $5.00

Shipping Weight 10 lbs

CAN BE SHIPPED BY EXPRESS ONLY

TALKING TIRU LAND AND WATER

(Continued from page 505)

at either end. The two microphones face each other and are connected in series-parallel with a battery and a differentially wound telephone speaker. Suitable to the angles are fitted to the apparatus, which instantly indicate the angle, both vertical and horizontal. A nebulometric bubble happens to rest when a certain measurement is being taken.

Considering that the two differential windings of the telephone receiver are connected so as to oppose each other, any sound waves traveling thru the ground and reaching the gear exactly at the same instant, will cause a total cessation of sound in the receiver, when the 2 bar carry the two microphones is exactly at right-angles to the direction from which the sound proceeds. The position in which the microphone bar indicator points toward the enemy’s trench will be the one to be attacked, either by counter-mining or by a direct raid on the enemy trenches. This measurement gives the horizontal direction or angle from which the sound is emanating.

To determine the vertical angle or the dip of the direction from which the sound emanates, the central vertical rod is rotated thru 90 degrees of the pivoted microphone bar, and is tilted until the sound on the ground is such at which the angle or dip is indicated on the vertical index dial of the instrument. By taking another reading every thirty feet down the trench, the location from which the sound proceeds may be determined in the same manner, and its point of origin will be that point which the two lines of direction, so determined, meet, and its distance can then be instantly calculated (or computed on the rule) by trigonomical means, with which all military men are thoroughly familiar.

POPULAR ASTRONOMY.

(Continued from page 463)

globular cluster is composed of thousands if not hundreds of thousands of individual suns, sun in size, sun in brilliancy. They appear to be systems that have reached the height of development in which they are comparatively settled and there is as yet no sign of an alteration. They resemble the spirals in having exceptionally high velocities of translation thru space, but they do not show in number about seventy being catalogued up to the present time as thousands of the spiral nebulae. Now these globular systems show a symmetrical distribution with reference to the plane of the Milky Way which appears to form an equatorial belt that the globular clusters and the spiral nebulae avoid. The width of this equatorial belt wherein lie the vast majority of all the stars, including our own sun, and the great majority of the nebulae is ten thousand light years, while its diameter appears to be fully three hundred thousand light years. Symmetrically distributed with reference to this belt seems to be evidence that they are units in one great universe in which the Milky Way occupies the equatorial position. This has a direct bearing on both the age of the universe and the theory of the spiral nebulae. The spirals as well as the globular star clusters lie at great distances outside the equatorial belt, and we can see the evidence of being affected by it since they tend to cluster in greatest profusion in the vicinity of its poles as if avoiding the strong gravitative attractions existing in the equatorial region.

It would appear then that the spiral nebulae are not "island universes" in the sense that they are Galaxies similar to and independent of our own Galaxy, but are rather secondary formations in a universe in which the Milky Way occupies the position of an equatorial belt. The spiral nebulae are possibly conglomerations of stars and nebulae that have at some time broken away from or past thru the equatorial region of dense star clouds and gaseous nebulae and are moving rapidly away from the central plane since the antapex of their radial velocities is the center of the equatorial area.

According to Dr. Shapley of the Mt. Wilson Observatory, who has recently made extended investigations of the globular clusters, the spiral nebulae will have penetrated this equatorial region from the Milky Way the Great Cluster in Hercules, one of the nearest, will reach the plane in less than thirty million years. These intervals of time are very short in the general universe and he concludes that the central region has been penetrated by the globular star clusters many times in the past and that the moving star groups that are found within this equatorial region such as the Hyades and the Ursa Major star group may be remnants of clusters that attempted to cross the plane of the Milky Way.

The most acceptable theory advanced up to the present time in explanation of the spiral nebulae therefore assumes that they are "island universes" that resemble our Galaxy in size and extent but rather subordinate units in one vast universe in which the majority of all the stars, the planetary nebulae, and the great irregular nebulae from which the stars are formed, occupy the central belt. At great distances beyond this region lie the globular star clusters and the spiral nebulae.

The origin of the spiral nebulae and the cause of their peculiar structure is still under investigation, but it is generally believed to be enormous conglomerations of stars and nebulous bodies having a motion of rotation as well as a velocity of translation thru space that is tremendously high.

(Next installment will appear in November issue)

THE HOW AND WHY OF RADIO APPARATUS.

(Continued from page 472)

metal cover on the transmitter, and placing the wireless receiver diafragma (with its cap removed, of course) up against the "Detect- phone" transmitter diafragma. In fact the two may be glued together so as to have a practically single period of vibration, similar to the method utilized in building tele-developers. By this means, and taking care not to spill the carbon granules out of the microphone, the receiver and transmitter should be bound together firmly with minute and exactitude. The effect, of course, will be seen for the second receiver and transmitter, stage D. At Fig. 4 there is shown a simple method of supporting the ground-proof diafragma of the detector of stage C; by suspending them on 4½ inch rubber bands from an arm. This prevents extraneous vibrations from affecting the ultra-sensitive

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
transmitters. This system has been applied commercially, and an amplification value of 15 times the initial received strength of signal has been obtained.

The "Helmholtz" acoustic resonator has been successfully used to boost the strength of signals as heard in the radio receiver, the glass bell of the resonator being placed close up to the receiver opening as shown in Fig. 3A. It is particularly suited to use on regenerative valve sets, where a variable capacity is employed to vary the number of beats. The receiver used is preferably a standard 1,000 or 1,500 ohm type.

The large opening of the resonator should fit over the opening in the telephone receiver cup. The pure acoustic resonator responds only to a certain frequency for each size of bulb; therefore the resonator used should approximate the beat frequency used. Also the variable capacity in the audion circuit should be varied until the beat frequency created permits the Helmholtz resonator to be in resonance with the receiver. On spark signals and a crystal detector a resonator corresponding to the pitch of the incoming signals should be selected in each case.

Fig. 5-2 illustrates an adjustable resonance amplifier which has been used with beneficial results, it is said. The resonance tube comprises two tight-fitting brass tubes, one for sliding within the other and the complete tube member joining a microphone and receiver, for example. The resonant frequency to which the tube will respond may be changed by sliding the inner tube in or out. The law of frequency for these tubes can be found in any good text-book on physics. Various sizes of tubes should be tried.

The "compest air" amplifier. A new and extremely simple form of intensifier for telephonic, telegraphic, and photographic signals or sounds in the Parson's compressor air valve, shown in Fig. 6. A radio or telephone receiver, R, is conected by a rod, as shown, to an air piston or other form of valve. Whenever the receiver diaphragm moves, or signals are being received, it actuates or moves the air valve controlling the flow of compressed air to a loud talking diaphragm, I, connected to a suitably large horn. This is only a general description of this interesting amplifier, and further information can be gained from the phonograph companies using it, also by consulting the records of the Patent Office or back files of the Electrical Experimenter (October, 1915, issue, page 265).

The "Lowenstein" Electro-magnetic Amplifier. This apparatus as designed by F. L. Lowenstein, of New York, will operate on any receiving detector and is recognized as the most sensitive detecting device for electric current of this particular type ever constructed for commercial use, as it will be deflected by a current of 1 microampere (1 millionth of an ampere).

This super-sensitive relay is illustrated in Fig. 7. The moving element $C$ is wound with a coil of extremely fine wire and carries a contact D which makes connection with a small pool of mercury E, when the armature is deflected. The moving part is supported on two jewel bearings to eliminate friction and the connections to the moving coil consist of two very fine helical copper springs at both ends. Two small discs, F, F, are provided to regulate the swing of the coil, which is mounted between the pole-pieces, E, that are energized by the magnets shown at A, A, A. The coils are so connected that the two pole-pieces will have different polarities, thus forming an X, and the current for these magnets is obtained from a 110 volt direct current supply and is led in thru the wires G.

EASTERN RADIO INSTITUTE

38 B Boylston St.

BOSTON, MASS
The operation of this remarkably sensitive relay is as follows: The powerful electro-magnets are first excited and the moving coil is connected to the receiving circuit. The place of the regular ‘phonograph terminals H’ and a calling device, such as a bell, at the terminals I. When the coil C is excited by the feeble current produced by a recorder, which, of course, is received by the other instruments from the radio transmitting station, it will turn, and its lever D will make contact with the coil of mercury E, thereby completing the circuit which causes the calling device to operate. The bell can be replaced with a tape recorder by which messages can be rapidly copied. This, of course, must be operated at a slow speed, as the moving coil has an oscillation period of 1/2 of a second. The oscillating frequency period can be changed by varying the distance of the levers F, F, and the coil. The ivory or bone cup in which the mercury is kept can be moved either forward or backward by operating a small thumb screw located at the end of the container.

The complete relay is supported on a table which can be rotated to offset any detrimental effects of the earth’s magnetic field. A suitable cover with a glass top is placed over the instrument to prevent any dust settling on the delicate moving parts. This device is capable of withstanding shocks and will work even when slightly jarred. For, it has been tested on moving vessels and the results were entirely satisfactory.

Altho the relay is adopted for radio work, it will be very useful in a laboratory where it is necessary to detect very minute or feeble currents. By mounting a sensitive microphone to make connection with the winding on the moving element of this apparatus it might then be used as a telephone relay, second only to the Audion in sensitivity.

The “Selenium” Relay. Until recently the most sensitive relay was the Siemens polarized relay, which would close its contacts when a current of less than 0.0001 amperes was carried. The new selenium relay invented by Mr. G. Allstrom is said to respond to less than 0.00000000001 (one hundred billionth) amperes of current. This would make it more sensitive than a telephone receiver, and experiments have shown that for wireless work it is well adapted for signalings and calling purposes. The instrument has been used in connection with electrolytic detectors, which were always thought to be too feeble for connection with telephone receivers. Loud, audible signals were never obtained so far with such detectors, but the Allstrom selenium relay makes it possible to use a sounder or tape register with any kind of detector, no matter how sensitive.

An extremely light piece of sheet iron, A, is hung between two platinum wires of the minute diameter of 0.0001 inch, etc. In the center of the iron sheet a small, very light mirror is cemented. An electro-magnet, B, when a current of high as 10,000 ohms, is placed instead behind the iron foil, so that the magnet core almost touches the iron.

Some distance away a sensitive selenium cell, S, is stationed. The cell itself is enclosed in a box, which at the front has a narrow slot. A source of light, Q, is placed behind the cell, and the room must, of course, be dark. By means of a parabolic mirror a beam of light is reflected upon the small suspended mirror on A.

This beam is reflected towards S, but as long as the foil A is motionless, the beam of light does not cross the slot.

However, a minute current—such as a wireless wave—passing through the windings of M, will magnetize its core sufficiently to turn the very light mirror on A, and the
"Humanize"
Your Talking Machine

The Ellis Music Master Reproducer

brings to life all there is in the record. It brings out the beautiful overtones which musicians listen for—and which are invariably lost with ordinary reproducers.

As one enthusiastic user says—

"There is more music in my records than I imagined possible until I discovered it by means of your Reproducer."

Another user says—

"The 'Music Master' Reproducer brings out the musical and tone coloring true to Life."

And another says—

"The reproduction of the human voice is wonderful and the rendition of violins as true as to the artist's performance as when making the record, even to the drawn touch of the bow."

Still another says—

"I would not sell my Ellis 'Music Master' for a thousand dollars unless I first got another equally good."

Words cannot convey to you an adequate idea of how much this wonderful little invention will do to improve the idea of reproduction unless you try it—compare the effect with any and all other reproducers you know of; then you will understand why every music lover wants an autograph who hears the Music Master Reproducer wants to own one.

The Music Master Reproducer is made for all machines which record and reproduce for circular E—which gives full details.

ELECTRICAL EXPERIMENTER

1918 ATLAS
1918 ATLAS WITH NEW WAR MAPS FREE
To the readers of the Electrical Engineer who take advantage of this offer now made in connection with Webster's New International

The Only Grand Prize (Highest Award) given to dictionaries at the Panama-Pacific International Exposition was granted to Webster's New International, and the Merriam Series for superiority of educational merit.

"The Supreme Authority"
The Merriam Webster
A Complete Reference Library in Dictionary Form—with nearly 3,000 pages and type matter equivalent to a 15-Volume Encyclopedia, all in a single volume, in Rich, Full Red Leather, or Library Buckram Bindings, can now be secured on the following remarkably easy terms:

THE ENTIRE WORK WITH 1918 ATLAS
DELIVERED for $1.00
and easy payment thereafter of only a few cents a week. (In the U. S. and Canada)
ON SUPERIOR INDIAN PAPER.

Reduced About One- Half

In Thickness

and Weight

India-Paper Edition

Printed on thin, orange, strong, superior India paper. This edition is only about one-half the thickness and weight of the regular edition. Size 12% in. x 9% in. Weight 6 lbs. (41 lbs. step-up).

Regular Paper Edition

Printed on strong book paper of the highest quality, being a close imitation of the regular edition. Size 12% in. x 9% in. Weight 16 lbs.

The only dictionary with the New Revised, Complete and All-Inclusive Dictionary. The ATLAS is the 1918 "New Reference Atlas of the World," containing nearly 500 pages, with 128 pages of maps beautifully printed in colors with marginal reference indices, late Census maps, Forest-Pest Guide, New War Maps, etc., all handsomely bound in red cloth, embossed.

"To have this work in the home is like sending the whole family to college!"

The ATLAS
Let Me Train YOU IN AVIATION
I want you to take up Aviation. Positions at good pay are going begging, because there are not enough trained men to fill them. LET ME TRAIN YOU for some of these big positions in paying wages. I know the game, for I have been flying for years. My advice to you is:

Home Course in Aviation
Send order for our FREE BOOK and I will write you a personal letter, along with it. I will tell you some INSIDE facts about this great industry. You try to get right in.

Address as follows:

To whom mail this Coupon now.

Please send me at once all obligation or expectation of any duty in connection with your "5,000 English Words" or any other reference book. I promise to send you a free copy of "The Science of Aviation," also part of your ATLAS library.

Pencil in Name of College or Institute.

-mail order form the ready.

LEARN TELEGRAPHY QUICKER EASIER

Adjustable Buzzer Practice Set

Quickly Gives You Speed—No Tools Needed—A Touch of Your Finger Adjusts It. This practical "Buzzer" settles that recording MISTAKES enables you to learn at twice the normal speed. Most people take longer time than ever before thought possible. A touch of your finger to the Buzzer when you have finished with it returns the Buzzer to its original position. The adjustable Buzzer may be used on any device that vibrates with a consistent rate of speed. The greatest improvement in practice and the key to the correct formation of printed letters find a ready application in the combination of the adjustable Buzzer and the Morse Telegraph Practice Set.

Price $3.50 WITH BATTERY AND WIRE

Complete Ready for Use, Immaculate Delivery, Money Refunded if not satisfied. Send for illustrated folder.

Not Enough Men for These $5,000 Positions

An Important Letter
From the President of the American Commerce Association

I am writing this letter as a last resort to see if we cannot secure more men willing to qualify for traffic positions paying $2,500 to $10,000 a year.

How important is the trained traffic man's work can be seen by these few cases out of thousands which occur every day. A concern in South Chicago had been shipping about 200 cars of coke from Connellsville to their smelters. Some time ago a traffic expert succeeded in getting a rate adjustment which resulted in a saving of about $5,000 on each car. Thus on this one item alone a saving of over $360,000 a year was effected.

In St. Louis, through mis-routing of freight, errors in reconsigning cars and undercharges on shipments, a railroad lost over $27,000.

A traffic expert discovered that freight rates paid by the Meeker Coal Co. were legal, but exorbitant. A ruling secured from the Interstate Commission resulted in a refund of $120,000.

There are about 50,000 large business corporations and about 400,000 small shippers which must be protected by competent traffic men. These concerns have freight expenses running from a few thousand dollars to many thousands of dollars monthly. Yet in the entire country there are only a few hundred men actually competent to save the money now being wasted through lack of efficiency in applying the Government Freight Rate System.

Realizing the crying demand for trained traffic experts, and seeking relief, the American Commerce Association—a national organization OF traffic men, FOR traffic men, BY traffic men—offers to give men the training required to make them competent to handle the problems of most economical distribution. This instruction is given by mail and can be studied in spare time at home. The most complete and thorough training is given, and, through the Association, costs but a few cents a day.

Through its Advisory Council, every member of the American Commerce Association receives the help of the most prominent traffic men in America.

It is impossible to go into details in this letter, but the Association has published a remarkable book for free distribution which explains everything in detail and tells how any one may quickly learn the new profession of traffic management. If you are at all interested in getting into this highly profitable field, paying salaries of $2,500 to $10,000 and more, write for the remarkable free book. Please state whether you are a beginner or whether you have had previous traffic experience, and give your present age and occupation, also your telephone number. Address American Commerce Association, Dept. 5011, 206 S. Wabash Avenue, Chicago, Ill. (American Commerce Bldg.)
the frequency of the radio current to that of the controlling current. For telephone control the amplification ratio varies from 100 to 1 up to 350 to 1. It has been successful in control of the output of a 75 kilowatt radio frequency alternator.

With this amplifier it has been possible to effect a variation in the antenna energy from 5.8 to 24.7 kilowatts with a variation of control current of but 0.2 amper. Think of effecting such a control—namely 37 kilowatts variation—by means of a telephone transmitter.

This covers the important types of radio amplifiers. Radio investigators and experimenters generally will, however, undoubtedly find of interest the following articles which have appeared in this journal. If you cannot obtain a copy of the desired issue from the publisher you can see them at your local library in most cases.

Compressed air amplifier applied to phonograph. Oct., 1913, issue.

A new Magnetic Radio Relay—How to build one and close a long circuit for tape recorder or other apparatus. By Ralph A. Mead. May, 1916, issue, page 162. (Note—the magnet coil mentioned gives no indication of the size; each magnet coil contains 11 ounces of Ne. 36 R & S. 6.4 gauge enamelled copper magnet wire, giving a resistance of 7,650 ohms for the two spools in series.)

Selencium, Relay. See present number of ELECTRICAL EXPERIMENTER, page 471.

Audio Amplifier Action—Exhaustive discussion of electronic movements, etc. Most complete article on this phase of the vacuum valve available. August, 1916, issue.

THE PHENOMENA OF ELECTRICAL CONDUCTION IN GASES. Continued from page 465.

graphic paths it can be seen that they have encountered no force strong enough nor any mass great enough to turn them aside in their passage thru many thousand molecules until the particle had slowed down a great deal. Another interesting point is evident here in the fact which can be obtained from the photographic path that the slower the ion is traveling the slower ions it will produce, and the faster it travels the more likely it is to pass completely thru a molecule without bringing anything to a rest in the way in which an electron may pass thru a molecule has been illustrated in a previous paper by the way in which a pebble may be slowed down by the circle described by a rapidly revolving ball on a string without either touching the ball or the string. Similarly two molecules consisting, as in Fig. 5, of electrons rotating about nuclei, may pass thru each other without either of the two nuclei or the two electrons coming to a rest. The faster electron is moving in the directions of the arrows the less likely it is that the rotating particles will collide.

The fact that the paths of the ions in Fig. 4 is quite different from the others shows that ionization may be of several different kinds, and in no way is this shown and explained more clearly by these phonographic paths. This brings up the question as to just what the mechanism of ionization is. There is little doubt but that the beta particle produces ions in passing through molecules of air by ejecting an electron from each molecule, either by collision or by the force of its field. As the electron remains inert along the path of the ionizing particle it seems to have been suddenly loosed rather than forcibly ejected as by collision. The action of the

EXPERIMENTERS!

$5.

The Boy's Electric Toys

No. EX2002

"The Boy's Electric Toys" contains enough material to make and complete over twenty-five different electrical apparatus without any other tools, except a screw-driver furnished with the outfit. The box contains the following complete instruments and apparatus which are already assembled:

Student's chronic plunge battery, compass-galvanometer, solenoid, telephone receiver, electric lamp. Enough various parts, wire, etc., are furnished to make the following apparatus:

Electromagnet, electric cannon, magnetic pictures, dancing spiral, electric hammer, galvanometer, voltmeter, hook for telephone receiver, condenser, sensitive microphone, short distance wireless telephone, test battery, shocking coil, complete telegraph set, electric revolving machine, electric buzzer, dancing faces, ringing telephone, mysterious dancing man, electric jumping jack, magnetic geometric figures, oscillato, erratic pendulum, electric battery, thermo-electric meter, visual telegraph, etc., etc.

This does not by any means exhaust the list, but a great many more apparatus can be built actually and effectively.

With the instruction book which we furnish, one hundred experiments that can be made with this outfit are listed, nearly all of these being illustrated with superb illustrations. No other materials, goods or supplies are necessary to perform any of the one hundred experiments or to make any of the 25 apparatus. Everything can be constructed and accomplished by means of this outfit, two hands, and a screw-driver.

The outfit contains 16 separate pieces of material and 24 pieces of finished articles ready to use at once.

Among the finished material the following parts are included: Chromic salts for battery, lamp socket, bottle of mercury, core wire (two different lengths), 4 bottle of iron filings, 3 wires of wire, carbon, a quantity of machine screws, flexible cord, 2 wood bases, glass plate, paraffine paper, binding posts, screw driver, etc., etc. The instruction book is so clear that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the layman with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The net weight of all the outfit is 14 x 9 x 2 1/2 lbs. Shipping weight, 10 lbs. No. EX2002 "The Boy's Electric Toys" outfit as described...

EXPERIMENTERS!

Student's Chronic Plunge Battery

This is an ideal battery for experimental work where a very powerful current is not required. The battery will hold a 100-watt lamp for several hours. Can be used as a source of current for all experiments requiring a small current. A current will make a spark of a single twist of the handle. Can be used to give a steady current, and in the electric apparatus, the electrolytes, no materials are used when battery stands idle.

Best Amalgam Zinc only is used, as well as a highly porous carbon to ensure a steady current. We furnish enough chloride salt for 30 charges. Full directions for operation and care of battery included. Each handle should be turned only once. Turn only to 100-watt lamp. Each handle turn gives a spark. No accidents can run out of this battery if kept by accident. This makes it an ideal student battery. Price...

The "Electro" Radiotone High Frequency Silent Test Buzzers

This instrument is a wonderful high pitched MUSICAL NOTE in the receiver, impossible to adjust. Does not sound unless a current is flowing through the radiotone. In ordinary telephone operation, is not an ordinary buzz, resonating in some manner. The RADIOTONE has a single tone and sounds vibrating at a very high speed, adapted to its most efficient frequency at the factory. Hard silver contacts are used to make the instrument last practically FOREVER. The RADIOTONE IS SILENT. In fact, it is so silent that you must place your ear on top of it to hear its beautiful musical note.

The RADIOTONE will be attended at all times and new battery contacts will be supplied to you every month. The RADIOTONE is sent to you complete, and when received we will send you a complete outfit, together with a description of how to use the RADIOTONE in all apparatus. The RADIOTONE is a very useful instrument to have in your receiver. To hear the tone, there is absolutely nothing to do. With the radiotone, a toy and one day old "888"... Price...

The "Electro" Codophone (Patents Pending)

What this instrument is capable of is beyond description. The "Electro" Codophone is positively the only instrument made at the present time that when used as a telephone gives a 100 cycle signal exactly as heard in a wireless receiver. The "Electro" Codophone is a handsome, well made instrument, fool proof, and built for hard work. Contacts are of hard iron 1/8 inch in diameter, and the instrument is complete and ready to install with any telegraph or telephony office in the country.

The "Electro" Codophone is a handsome, well made instrument, fool proof, and built for hard work. Contacts are of hard iron 1/8 inch in diameter, and the instrument is complete and ready to install with any telegraph or telephony office in the country.

THE PHENOMENA OF ELECTRICAL CONDUCTION IN GASES.

(Continued from page 513)

alpha particle is just like, and it also seems that an electron is lost from each molecule through which the alpha particle travels, and in some cases several may be lost, which might be expected from the greater size of the alpha particle.

In the case of the short ether waves, say X-rays, the electrons seemed to be very forcibly ejected, for they break off from the main path and every branch indicates the point where a collision took place and a new ion was produced. Hence the path of a ray of X-rays thru air is an intricate network.

Just why ether waves produce this violent ejection in contrast to the passive ionization left by the path of alpha or beta particles remains a mystery.

In connection with the older molecular theory molecules were considered to be perfectly plastic so that on colliding with each other they bounced back with exactly as much energy as before. This assumption was necessary because if it were not true the molecules of any gas would slowly lose their energy and would fall to the bottom of their containing vessel as inert particles.

If the energy at each collision energy would be lost and the pressure would gradually decrease to zero. If we investigate the conditions of collisions it is apparent that reflections do not always occur. The molecules might pass thru each other under proper conditions, or the reaction of the gases so that all the energy of one is used in producing ionization and that one becomes inert, or they might be reflected. If the gas particles are reflected it may be from one or both of two causes:—The electric fields of the particles within the atom may oppose and repel each other, or some imperceptible centers more solid and material than electricity, if there be such, may collide and rebound. The fact bears repeating that an alpha particle may pass thru a million molecules before experiencing such a force or such a material center. The faster the molecules travel of course the more chance it has of going completely thru another molecule. Ordinary gas molecules move at such relatively low speeds that they do not really produce reflection. The fact that the collision seems perfectly elastic is still difficult to explain unless as explained above, this reflection is due to the repulsion of electric fields; then the only loss of energy would be due to the ether and the other is considered frictionless.

The field of the ionization of gases is one of the most promising in all science. In these papers the most important phenomena have been considered relative to electricity in gases and besides adding to our practical scientific knowledge and intellectual resources which it throws on the real electrical nature of matter and electricity is invaluable.

(Conclusion.)
### MAGAZINES GOING UP!

#### Your Last Chance For Old Prices

With the next issue, the price of the EXPERIMENTER, as announced on another page, goes to $2.00 a year. This is positively the last month in which the ELECTRICAL EXPERIMENTER can be secured for $1.50—-and for considerably less if clubbed in connection with other magazines.

With the tremendous advances in the price of paper, it is quite certain that the ELECTRICAL EXPERIMENTER, as well as the rest of the magazines, will have to go still higher, before another six months. By subscribing now from one to five years, YOU POSITIVELY WILL SAVE BIG MONEY.

The prices below are unquestionably the lowest for standard magazines that it is possible to obtain anywhere. Only by a special arrangement with the publishers are these prices possible and they are good only until October 31st, after which date all prices as given on this page are withdrawn. Make up your list at once—do not delay. If you are already a subscriber and your subscription to the EXPERIMENTER runs for a long time, you may subscribe for any other magazine by deducting the price of the EXPERIMENTER from the clubs at the rate of $1.25, (the special price allowed in clubbing with other magazines). Thus you can make up any club yourself of as many magazines as you wish from the list below.

All prices quoted are for subscribers in U. S. only. Canadian and foreign subscriptions require additional postage.

Electric Supplies & Appliances

Electrical Tattooing Machines and supplies, complete for five cents. Directions, 10c. Gilbert & Chesterton, Binghamton, N. Y.

Electricians. Send $1.00 for 16 blue prints of Motor, 20 Mark three-phase, and 6 D. C. or set of all A. C., D. C., and direct current. Dr. Roziere, 625 E. 152, Conn. Connecting and wiring made easy. Superior Electric Company, Lock Box 1932, Pittsburgh, Pa.

Salesmen for Rice: Two highest sensitive cells with direction for same. One Dollar, Rice, Experimental Laboratory, Good Land, L. I.

A Binder for The Electrical Engineer will preserve your notes, receipts, etc. Postage on 3 lbs extra. Send for one today, Experimenter Publishing Co., 251 Fulton Street, New York City.

Photo Developing

Kodakets: How would you like to get a 5 x 7 enlargement of your best negatives free? Dr. Pike, Kodakets, home developed and colored. Free. Films developed at 90c per roll, prints 3c, 5c, and up. Address Dr. Pike, 30802 South, Chicago, Ill.

Mail us Ic with any size file for development and 6 velvet prints. Or send 6 negatives any size and 15c for 6 prints. 8 x 10 mounted enlargements, $2.00. Send to Photo-Raism, Ross Photo Finishing Co., 255 Bell Ave., Roanoke, Va.

Scientific Exchange Columns

You undoubtedly have something you'd like to buy, sell or exchange. In your attic, or workshop, or some far corner of your closet, you probably have some long-forgotten articles, useless to you now, but very useful to someone else. We have received from 3,452 "wts" published in these columns during the past five years, only fifteen complaints were reported to us, and each one was adjusted to the full satisfaction of the complainant.

We hereby announce that henceforward we accept all orders. No advertisement for less than 50 cents accepted. We reserve the right to accept or reject at our discretion.

Wanted—Bicycle—motor attachment or motor-wheel. Harold Lambert, Haverstraw, N. Y.

Fifty Dollar Course in Salesmanship—Will teach you how to sell electrically, how to meet your competition. E. W. Minor, Sargent St., Hartford, Conn.

Wanted—Different sketch or model for Electrician's tools. Will buy or swap for set Hawkins' Electrical Guides. Irving Hayman, 182 South St., Brooklyn, N. Y.

Wanted—Bicycle—motor attachment or motor-wheel. Harold Lambert, Haverstraw, N. Y.

Wanted—A Henderson or other make motorcycle or engine. What have you? A. W. Vogt, 225 West 24th St., New York.

Wanted to buy Perforating Telegraph Recorder, lately sold by Electric Importing Co. Box 92, Crestline, Pa.

Wanted—Shop—To rent. Will pay a reasonable rental. Harry Switer, Drexier, Ohio.

Wanted—12000 W. Missouri Ave., Chicago.

Wanted—A Henderson or other make motorcycle or engine. What have you? A. W. Vogt, 225 West 24th St., New York.

Wanted to buy Perforating Telegraph Recorder, lately sold by Electric Importing Co. Box 92, Crestline, Pa.

Wanted—Shop—To rent. Will pay a reasonable rental. Harry Switer, Drexier, Ohio.

Wanted—12000 W. Missouri Ave., Chicago.

Exchange—Courses "Mechanical Engineering," "Electrical Engineering;" Combined Lathe; Saw-Grinder; Emery Wheel; Bobsch; Spitting racing magnetos; typewriter; automobile generator; mechanical drafting equipment; fine Clarinet. Wanted—Wanted—cutting Lathe; Chemical Laboratory; Wireless; I. C. S. Chemical Laboratory; Saw-Grinder; Emery Wheel; Bicycle; Saxophone; Telephone. What? H. S. C., Box 144, Anderson, Indiana.

Wanted—A good 1 or 15 k. w. sending transformer. Will pay $300. Donald Pratt, 247 Faraug St., Chicago, Ill.

Sell—Each usually used: H. P., 110 D. C. folding machine motor, $15. Morelock 120 m. F. Variable and seee Packs, $10; Electric Stand. $3. Gilbert Miller, Delphos, Ohio.

For Sale—814 Erector, $8 or swap. Andrew Ellis, Kirkville, Mo.
Partial List of Subjects Covered

Complete Electrical Education Yours for Only 7c a Day!

Here at last in book form is the new way to learn electricity. All that has been learned about electricity is clearly explained in the Cyclopaedia of Applied Electricity — 7 massive volumes, completely indexed. Written by 27 of the country's foremost authorities, in such easy-to-understand language that learning electricity through this library is more fascinating than reading a novel. And you can have this remarkable electrical education in book form for only 7c a day, and at a bargain price.

7 Massive Volumes Shipped Free

These 7 splendid volumes will be sent to you promptly on receipt of coupon. Examine the books in your own home. Read page after page. Note that they are not thin handbooks, but thick, encyclopedia-size volumes, handsomely bound in half-morocco leather, gold stamped. Each one measures 7 by 10 inches, and is 2 inches thick. Over 3,000 illustrations are contained in the 3500 pages. The entire set will be shipped to you, without a penny's deposit, for free examination.

Not One Penny in Advance

Just mail the coupon. When the books arrive read all about Elements of Electricity, Electrical Measurements, Underwriters Requirements, Theory, Calculation, Design and Construction of Generators and Motors, Dynamo-Electric Machinery, Lighting Machinery. Read about every electrical process from wiring bells to wireless telegraphy. Send no money now. If after examination you decide to keep the books pay on easy terms of only 7c a day.

This Bargain Offer Must End

Regular price of these pay-raising books is $15.00. If after examination you decide to keep the Cyclopaedia of Applied Electricity pay only $2.00 a month until the special advertising price of $19.80 has been paid. With the books, a year's Consulting Membership in the American Technical Society is included free. Regular price of this membership is $12.00. It includes the advice of a corps of electrical experts on any questions you may want answered for a whole year free. Mail coupon now. See the books before you decide to buy. You don't risk a penny. This generous offer cannot be continued indefinitely as raising prices of paper and printing will soon force us to increase the price. Mail the coupon this very minute.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.

Experts Wanted

Electrical Engineers, Substation Operators, Trouble Men, Switchboard Operators and Dynamo Tenders are wanted by light and power companies everywhere. The demand for their services exceeds the supply. Why not prepare yourself to your spare time—for a job paying $1,000 to $5,000 yearly? The Library of Electricity will give you the knowledge you need—in plain everyday language.

American Technical Society
Dept. E 3388
Chicago, U. S. A.

Please send Cyclopaedia of Applied Electricity for seven days' examination, I to pay shipping charges. I will send $2.00 within seven days and $2.00 a month until I have paid $19.80 or notify you and hold the books subject to your order. Title not to pass until fully paid.

Get Started Now
in the
Industry of the Future

There is an opening for you at once in one of America’s foremost Aircraft Plants

There is a place for you in our New Brunswick (N. J.) or Long Island City Plant where you can earn good wages at the start, serve your country, and at the same time fit yourself for a good position in what is rapidly becoming the foremost industry of the world.

Here is your opportunity to make a place for yourself in a young and growing industry that promises to offer even greater opportunities than were opened up in the pioneer days of the automobile.

Skilled Mechanics and Operators Needed

At present we are engaged solely in the manufacture of aero-plane motors for Pershing’s Army.

To meet our ever increasing schedule of production, we must have the man power to operate the machines in our various departments. We want your help. We want skilled mechanics, machine operators, inspectors, draftsmen, etc. We will pay good wages for the right men.

Now is the time for mechanically skilled men to get into an essential fighting industry.

Our Offer to Men Not Technically Trained

You do not have to be a skilled mechanic to get started with us.

If you have the right spirit and the determination to learn, we will take you on and train you at our expense in our School of Instruction.

Not only will we give you, free of charge, a full course of practical instruction under the supervision of competent instructors, but we will pay you while you are learning.

When you have completed the course, which takes about ten days, we will pay you full wages prevailing in the factory.

Living Conditions Good

Living conditions in New Brunswick and vicinity are being bettered every day. Every Wright-Martin man will be able to count on a comfortable and congenial place to live. Moreover, the Government is now building 200 houses especially for war workers at Wright-Martin and other factories.

The company provides for social and recreational activities for everyone. With baseball, football and track athletics, picnics, concerts and dances, there need be no dull times for you or your family in New Brunswick.

One Hour from New York City

New Brunswick is just one hour out of New York on the Pennsylvania. It is within short commuting distance of Newark, Elizabeth, Trenton and Philadelphia.

Your Duty Is Here

In fairness to yourself you can’t afford to pass up this opportunity to advance yourself and serve your country, too.

Write, phone or apply in person to Employment and Welfare Department, Wright-Martin Aircraft Corporation, New Brunswick, N. J., Div. Cl.

Long Island City Plant

Our new Plant at Long Island City has openings for the following:

**TOOLMAKERS—** Toolroom Machinists and Grinder Hands, Tool Temperers, Tool Trouble Men.

**JOB SETTERS** for the following:

- Azme, J. & L.
- Gisholt
- Gridley Machines
- Warner & Swasey
- Pratt & Whitney
- Creasey & Whitney
- Internal and External Grinder Hands.

Apply at once, Borden & Starr Aves., Long Island City.

E. Nov,


Most of your time is mortgaged to work, meals and sleep. But the hours after supper are yours, and your whole future depends on how you spend them. You can fritter them away on profitless pleasure, or you can make those hours bring you position, money, power, real success in life. Thousands of splendid, good-paying positions are waiting in every field of work for men trained to fill them. There is a big job waiting for you—in your present work or any line you choose. Get ready for it. You can do it without losing a minute from work or a wink of sleep, without hurrying a single meal, and with plenty of time left for recreation. You can do it in one hour after supper each night, right at home, through the International Correspondence Schools.

Yes—You Can Win Success in an Hour a Day

Hundreds of thousands have proved it. The designers of the Packard, Ford, Simplex and hundreds of other Engineers, climbed to success through I.C.S. help. The architects of the great buildings, building and hundreds of Architects and Contractors, won their way to the top through I.C.S. part-time study. Many of this country's foremost Advertising and Sales Managers prepared for their present positions in spare hours under I.C.S. instruction.

For 26 years men in offices, stores, shops, factories, mines, railroads—every line of technical and commercial work—have been winning promotion and increased salaries through the I.C.S. Over 100,000 men are getting ready right now in the I.C.S. way for the bigger jobs ahead.

Your Chance Is Here!

No matter where you live, the I.C.S. will come to you. No matter what your handicaps, or how small your means, we have a plan to meet your circumstances. No matter how limited your previous education, the simply written, wonderfully illustrated I.C.S. textbooks make it easy to learn. No matter what career you may choose, some one of the 290 I.C.S. Courses will surely suit your needs.

Make Your Start Now!

When everything has been made easy for you—when one hour a day spent with the I.C.S. in the quiet of your own home will bring you a bigger income, more comforts, more pleasures, all that success means, can you afford to let another single priceless hour of spare time go to waste? Make your start right now! This is all we ask: Without cost, without obligating yourself in any way, put it up to us to prove how we can help you.

PRACTICAL
INSTRUCTION
Trade and Engineering Schools
Dept. 20Y, 39-51 E. Illinois St., Chicago, Ill.

Thousands of skilled Electricians are needed. The demand is becoming more urgent every day. The Government is employing every one they can get which is causing a great scarcity throughout the country and big salaries are being paid everywhere. Right now is your big opportunity. Make up your mind now to prepare for one of these big jobs and then get here as quick as you can for your training.

Earn $100.00 To $300.00 A Month

In the Electrical business, Come here where you will be trained in these great $100,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

DRAFTED MEN READ THIS

It will only be a short time until you are called into service. This is a war of skill, brains, and machinery. Uncle Sam must win this war and must have tens of thousands of men skilled in modern trades and professions such as Electricity, Drafting, Plumbing, and Sanitation. Such men will be quickly recognized and given an opportunity to rise. It is not too late for you if you act at once.

In most cases those of our students in the draft, who have been called before completing their course, have been given an extension of time by their board sufficient to finish their course, owing to the great need of trained men in these lines in the Government Service.

ELECTRICITY

AS EXPERTS KNOW IT

Learn electricity as you would in actual PRACTICE—in accordance with the methods employed by the highest paid electrical experts in America.

The New McGraw-Hill Library of Practical Electricity contains the actual working facts which you need in order to succeed in the electrical field. Terrell Croft, formerly with the Westinghouse Company, makes the conquest easy for you.

A New Standard in Electrical Literature

The New Library of Practical Electricity by Terrell Croft marks a new era in electrical literature.

The great field of electrical engineering, with its limitless possibilities of using power, is brought to you in a form that makes success easy. The Library is a creation—an achievement that is without parallel in technical literature, because it sticks to actual practice throughout its 5000 pages.

$2 per month starts you to bigger pay

(ELECTRICITY—8 VOLS.)

Now is the time to master Electricity—Now is the time to prepare for a high salary

Old books won't do. Amateurish books won't do. Books compiled by "desk authors" or men with no practical experience will not serve your purpose.

Practical books are easiest mastered. Practical books, written by practical men, teach you accurately and rapidly. There is nothing in the Croft Library which you cannot understand. Terrell Croft tells you the secrets of success in electricity in plain words, figures and illustrations. Nothing is left to the imagination. There is no guesswork. There is no theory or higher mathematics.

Send now for these eight volumes. No matter how many books on electricity you possess, you are unfair to yourself unless you take advantage of this free examination privilege. No matter whether you are beginner or expert, these books will show you the clear road to success. Inspection will prove this.

McGraw-Hill Book Co., Inc.

239 West 39th Street, New York, N.Y.

Not one cent in advance—Just the coupon

Examine this new Library for ten full days without expense. Find out for yourself why it is now taking the lead in electrical book sales in America. Use the books as you see fit for ten days. Look at the hundreds of illustrations that clear up all the mysteries in electrical practice. Stick a couple of the volumes in your pockets, and refer to them during the day. Figure out in an instant the problems that have heretofore taken hours.

Then send us $2 per month for eight months, or return the set entirely at our expense. You risk nothing by returning the attached coupon.

[Entered as second-class matter March 1, 1915 at the post office at New York, N. Y., under the Act of March 3, 1879. Experiment Publishing Co., 233 Fulton St., New York, N. Y.]
We want ambitious men and women to have these remarkable Charts which are a visual demonstration of Chiropractic, the new science of Drugless Healing. This offer is now made to show the opportunities now open to Chiropractors. We also explain how we give a practical training by mail in this dignified, paying profession. If your desire is to enter an uncrowded field—if you want to achieve financial independence and social standing, at least investigate. Your request on the coupon below is all that is necessary.

**Drugless Healing**

The 72-page book and other literature we send on request shows the immense possibilities for Chiropractors of both sexes. The public is awakening to the fact that drugless to cure disease is in many instances, a fallacy. They are ready to welcome the practitioner who relieves and heals without nauseous dosing. The Charts show how the science of Chiropractic is applied. They reveal facts about the human body, instructive to the layman. You should obtain them without fail.

$3000 to $5000 a Year

Many Doctors of Chiropractic earn $5,000 a year and more; some upwards of $10,000. Dr. M. D. Moore of Ky., reports an income of $9,000 a year. Dr. L. H. Roche, New Jersey, $3,500; Dr. Hanna of Florida, over $5,000 yearly. What others are doing you should be able to do. A diploma gives you the same opportunity—evidence that you are master of a profession of dignity, prestige and influence.

**Our Lessons Teach You**

how to make Spinal Adjustments for speedy relief of

- Headache
- Neuralgia
- Indigestion
- Neuritis
- Lumbago
- Catarrh
- Epilepsy
- Fever
- Pleurisy
- Jaundice
- Constipation
- Dyspepsia
- Rheumatism
- Paralysis
- Asthma
- Etc., Etc.

**Be a Chiropractor Learn At Home**

By the American University system of instruction, you can become a Doctor of Chiropractic by studying in spare time at home or in class at the University. You do not require special talent or advanced education. A common school education and the ambition to succeed are all that is necessary. You will be trained under the direction of Chiropractic specialists who will teach you thoroughly the principles and practice of the profession. You will graduate with the degree of Doctor of Chiropractic.

**Mail the Coupon**

This coupon will bring full information about this new, interesting and profitable calling which any intelligent man or woman can readily master by our method—also information on how you can get these 22 instructive Charts. Send coupon for this free offer.

**AMERICAN UNIVERSITY**

Manierre Bldg., Dept 323 Chicago, Illinois

Wireless Around the World

In October first, 1918, the Marconi Radio Telegraph station at Carnarvon, Wales (England), established direct wireless communication with Sydney, Australia, a distance of 12,000 miles.

This is the first time that a complete radio message actually enveloped the entire earth in every direction. In other words, when the towers at Sydney in Australia were receiving that message, the waves came in on it from every direction of the compass, as a moment's reflection will make clear. Furthermore, in addition, the waves actually tumbled onto the towers from the sky, as well as from beneath the towers, thru the earth—a remarkable phenomenon, if we stop to think of it. For the etheric waves do not travel snugly around and over the earth, but a very considerable distance above it, as any proficient with a dirigible with radio receiving instruments on board can readily testify. On the other hand, every terrestrial station has its "return circuit" grounded to the earth for better results. Thus while the Wales-Australia radio waves were speeding around the globe in all directions as well thru the earth as thru the entire breadth of the earth, a minimum distance of 7,912 miles.

But if the waves traveled 12,000 miles around the earth, they probably traveled just as high above it, and perhaps very much further. We already know from experience that atmospheric conditions are the bane of the radio operator. Ionization of the air and barometric as well as electric disturbances of the atmosphere often make radio-communication impossible. Experiments and our present day knowledge of physics, on the other hand, convince us that if there were no atmosphere at all, radio transmission would not be only infinitely better, but the distance covered with a certain amount of power, could be increased very considerably. Radio waves, the same as light waves, belong to the same family. Both are electromagnetic manifestations of the ether. Both are equally hampered by the terrestrial atmosphere. Thus the best astronomical observatories are located on the highest mountain peaks. In such a position the astronomer can see much better, tho only one or two miles nearer his object, which, as for instance the planet Mars, may be 50 million miles distant. But the astronomer must thru only about 30 to 40 miles of air—this being the estimated thickness of the terrestrial atmosphere. On the other hand, our radio waves traveling around the globe, must speed thru 12,000 miles of atmosphere. Naturally, there is an enormous amount of absorption of energy, while the waves travel thru such a wide blanket of air; hence our suspicion, that as there is no such obstruction skywardly, the waves will travel infinitely farther into the free space where there is no atmosphere, once the paltry 30 to 40 mile air layer at Carnarvon is traversed. That these radio waves therefore, reach the moon, altho the latter is 238,850 miles distant, seems probable after these deductions.

The outstanding feature of this globe-enveloping wireless is, that the power used to accomplish the result is much less than was used years ago to send a message across the Atlantic. The answer is found in our modern radio receiving instruments, and their enormously increased sensitiveness. Electronic valve receivers, coupled to a six-step amplifier for instance, amplify a given signal over one million times! Such results were undreamt of even five years ago. It must be obvious that as receiving instruments become more and more sensitive from year to year, we require less and less power at the sending station. Just as the astronomer sees a hitherto invisible star, because of his more powerful telescope, so does the wireless range increase with a more sensitive receiver. The day is not far when we will be able to send a radio message around the world using only a few dry cells for the tiny power at the sending station.

H. Gernsback.
Master Electricity By Actual Practice

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

The Oldest and Only Institution of the Kind in America

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

Over 5,000 Students now holding Successful Positions in the Electrical World

5,000 of our students are today successful electricians.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions.

Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

At Last the Super-Tank!

HERE at last we have the super-tank. It was recently thought out and patented by one Anton Krzan of Chicago. This military device has considerable possibilities, and its field of activities is a wide one. It may be mounted on a powerful automobile truck or chassis, so as to be kept rolling over the country at high speed, and the while hurling forth streams of machine gun bullets, not to mention liquid fire and gas. This armored telescopic tank may carry searchlights for use at night. It can also be used as an observation post for the Signal Corps.

Of course, this armored tower could be well camouflaged so as to be hardly discernible even a few hundred yards away. The inventor describes one way of elevating the steel tower, whenever so desired, by the use of compressed air. He states that one man can elevate the tower section by simply turning the handle on a small air pump which compresses air at atmospheric pressure and forces it into a flexible chamber, which, as more and more air is pumped into it, naturally causes the tower sections to rise correspondingly. Where the super-tank is mounted on an automobile chassis, several other methods at once become available for elevating the tank as often as required. One of these is to connect it mechanically with the automobile engine thru suitable clutch mechanism and gearing. Another method is to have a separate gasoline engine unit,

New York's Novel $6,000,000,000 Liberty Loan Sign.

One of the most spectacular features of the Fourth Liberty Loan campaign was the moving picture of the big Wrigley Gum Electric Sign in Longacre Square, which occupied an enormous scale giving the total figures subscribed each day. This sign, the largest electric sign in the world, occupies the roof of a building on the west side of Broadway from 43rd to 44th Street. The sign is 200 feet long by 50 feet high, and is an artistic design, comprising more than 15,000 electric globes.

Mr. Wrigley donated the sign for the use of the Liberty Loan during the campaign and the concern who built the design and donated the Electric Scale which recorded the total subscriptions until the six billion was reached. The scale occupied the center of the sign and is 66 feet in length. In fact, it is a small section of an enormous dial which, if completed would be 332 feet in diameter. The arrow is 14 feet long, and the letters "BUY LIBERTY BONDS" are 5 feet high. The arrow was set electrically several times during the day, according to figures received on the long distance phone from Washington, and busy New Yorkers found it of great convenience to watch the progress of the subscriptions to the Fourth Liberty Loan by simply glancing at this huge sign.

There was a sign at the bottom of the big display stating that the space was donated by Wm. Wrigley, Jr., Company, and this

dynamo, and the dynamo to operate the electric motor. This corresponds to the steam-driven prime mover fitted to many of our new ships, and there is also at the present time an automobile on the market having this form of drive. One of its principal features and characteristics is greater flexibility owing to the wide range of speed available wherever an electric motor is used. This cannot be said of any steam or gasoline engine power unit, where the power is taken direct thru gears, or other more or less jerky mechanical means.

Not only does this super-tank have a steel tower, but it can be raised and lowered as it speeds along, and the tower may be rotated as desired. For this purpose the upper section containing the machine gun or other ordnance is mounted on roller bearings, so as to turn easily and quickly. A portable wireless outfit may also be carried and at any time often times would be of invaluable assistance in carrying out difficult maneuvers and battle formations, owing to the fact that the observer is elevated above the ground and thus has a clear view of the enemy lines. At first thought it might seem that considerable power might be required to raise a telescopic steel mast such as this, especially when it might be expedient to raise and lower it quickly for the purpose of keeping the enemy gunners guessing. If they should happen to get a "bead" on the moving, highly camouflaged super-tank, but such is not necessary. For the telescopic steel mast can be properly arranged with suitable balance weights in the same manner that our apartment house and office building elevators are, so that very little power would

Army Engineers' Corps a Giant of Efficiency.

The wartime organization of the Army Engineer Corps was revealed for the first time on June 27, by Major General William M. Black, chief of the corps, in an address before the American Institute of Electrical Engineers. General Black outlined the extent to which modern warfare is an engineering problem and illustrated his address with screen views of the activities of the Corps in France.

General Black said the present corps organization is composed of 8,000 commissioned and 200,000 enlisted personnel. New units created, he said, most of which are now in France, included: Five corps regiments, consisting of sapper, searchlight and sound-ranging troops; 43 sapper regiments and trains; 2 mounted battalions and trains, 5 pontoon trains, 4 inland waterway companies, 40 railway regiments and battalions for construction and operation of standard and light railways, 1 railway transportation corps, 1 highway regiment, 1 gas and flame regiment, 1 gas training service, 5 forestry and auxiliary forestry regiments, 1 surveying and printing battalion, 1 military mapping service, 2 supply and shop regiments, 1 water supply regiment, 1 quarry regiment, 1 mining regiment, 1 electrical and mechanical regiment, 2 crane operating companies, 1 camouflage battalion, 5 army companies, and 44 depot detachments.

General Black, who accompanied Secretary Baker to France, personally inspected army engineering projects there, said the majority of these units were serving with American troops, although some were attached to the French and British forces. He pointed out that 20,000,000 square feet of floor space are required to store 90 days' supplies for 1,000,000 soldiers and double that amount of open space. At one point of embarkation, he said, 375,000 square feet of wharf space had been provided to accommodate incoming troops and supplies, and he estimated that the transportation services which had to be constructed and must be able to handle the front 25 pounds per man per day.

Radium in Mexico.

A concession has been granted by the secretary of industry and commerce in Mexico for the exploitation of a deposit of gold, uranium and radium at Guada- lupe, in the mountains of the state of Chihuahua. All the machinery necessary for thor and extensive operation will be introduced. The government will receive 5 per cent of the gross output for the permission granted. This is the only deposit of these minerals so far discovered in the republic.

Almost automatic in its operations is a new cabinet for quickly developing X-ray photographs for dentists' use.
A Deadly Spiral Course Torpedo

DROPPING a missile from an airplane with sufficient accuracy such that it will hit a moving ship or other target is a very difficult matter at all times, and as may be readily supposed the number of "hits" registered under marine conditions is but a very small proportion of the missiles dropped. Therefore, a Yankee genius, Edward D. Priest, of Schenectady, N. Y., has taken out a patent on a clever spiralling course once it starts moving under its own power, to follow a spiral path of ever increasing radius. As the accompanying illustrations will make clear, it is only a matter of time when such a torpedo is bound to "get" you. Of course, if the torpedo should be near the end of its range, such as on an outside lap of the spiral and traveling somewhat slower in speed, the argument might be raised that the vessel could easily side-step with a disengaging striker which hits the water just before the nose of the torpedo, releasing the parachute, and in the next instant two specially devised rudders strike the water, and these are pushed upward; this action causes the propelling motor circuit to be actuated, and the propeller starts spinning. At the same time an electrical device begins functioning, which causes the rudder to slowly turn, which then forces the torpedo to follow a spiral path of gradually increasing radius. It is evident that if this were not done, and the rudders set at a given fixed angle, then the torpedo would proceed to follow a circular path of the same or constant diameter.

The torpedo is preferably propelled by compressed air, actuating a compressed air motor, the same as in the standard naval type of automobile torpedo of the Bliss-Leavitt pattern. The inventor provides for causing the torpedo to travel either partially submerged or on the surface, as desired.
3,000,000 Fish an Hour Without a Hook

ANY luck?” asks the habitual human machine gun. You can only answer him and say, “Yes, several thousand bites from our mutual friends the mosquitoes, but not a bite from the wily fish.” It is the same old story, but not so with the new Giant at the rate of ten miles an hour, this forward motion causes fish to be carried into the scoop and thence thru the throat of the scoop onto the electric conveyor, which carries the fish to the electrically operated sorting machine, where the different varieties and sizes are sorted, separated and sent on fish are absolutely fresh when they are placed into the ice-making machine and frozen, then they necessarily must be absolutely fresh when the boat is landed and the fish unloaded for consumption by the public. All fish that are of desirable qualities but are too small for use are allowed to pass

Fishing Machine, designed and originated by one Captain N. A. Lybeck, a sturdy follower of the sea from coast to coast. While on one of his numerous adventures of the deep, he was thrown into close relationship with an unknown specie of deep sea fish that had a searchlight eye with the properties of “mesmeristic” influence. After his safe extrication from this catastrophe he evolved the idea that this fish must exercise a hypnotic influence over its prey and here was the birth of his great idea,—namely, a giant fishing machine which would “hypnotize” the fish with powerful electric searchlights and a scooping device, which would run in the fish to the sorting tables; in other words, an electro-mechanical fisherman on an enormous scale.

How successful he has been can be judged from the illustration of his monster Fisherman. In action its operation can be described as follows:—When the engines are working and forging the boat ahead to the different respective packing bins.

The best of the selected fresh food fish are immediately, while still fully alive, frozen into solid blocks of ice in an electric refrigerating machine. The Government Bulletin that has been issued on this subject of cold storage lays stress on the fact that either the packing of a perishable article in ice or the refrigerating of the same by a cold producing machine will positively preserve the article in its exact condition at the time of refrigeration. Therefore if the uninjured back into their native element, where they may increase in size and numbers. This is made possible by the construction of the fishing machine and its scoop. The fish are caught and carried forward without any sort of injury; therefore if they are not of the kind that are wanted or are diminutive in size they can be returned and none the worse for their experience.

The hulls of the boat are tunnelled and streamlined so as to eliminate any disturbance of the water, which in some way or another gives notice to the sixth sense of the fish, if they have such a sense, that danger is lurking nearby. For that very reason you could have killed Tower when you brought him on that last fishing trip and while comfortably smoking our favorite mer- schaum he started to bark and run up and down the bank of the stream, scaring all of the fish away from your
How Ships Are Welded by Electricity

It is reported that Charles M. Schwab, Director General of the Emergency Fleet Corporation, is considering the construction of a totally electrically welded ship at an early date. It is undecided whether to make the initial experiment with a five thousand ton vessel or a barge. But in any event, the Emergency Fleet Corporation, which is now building vessels by the hundred for Uncle Sam, thus placing the American flag in every port of the world after the war, will undoubtedly adopt this form of building ships, if not altogether, at least to a large extent. For many years, and in fact as long as steel ships have been built, the plates on the hulls that the boats have been lapt over one another, and then held permanently together by passing red hot iron rivets thru perforations near the edges of the plates, the heads of these rivets being swaged over with either a barbed hand with a sledge hammer or else with a pneumatic riveting tool while hot. Some idea of what a tremendous job this riveting problem is may be gained from the fact that a typical day's record in riveting at Hog Island, America's newest and greatest shipyard, is 110,000 rivets per day.

The Emergency Fleet Corporation has thought so well of electric welding of steel ships, as followed by the English shipbuilders in a small way, that they have appointed an

Electric Welding Committee, which board has looked into the technical details and problems connected with the application of electric welding on such a gigantic scale as is required in welding the plates together on a five thousand to ten thousand-ton ocean greyhound, measuring five hundred feet long and standing sixty feet high on the ways—from keel to deck.

Briefly, there are two forms of electric welding which are being experimented with, and these are arc welding and spot welding. Arc welding gives great promise in the shipbuilding field, and has been largely used abroad and also to some extent in America, especially in railroad repair shops where a heavy direct current was easily obtainable. It was thus discovered that the process of arc welding was much cheaper and could be performed more rapidly than by any of the gas welding methods. Spot welding is now used extensively in many different industries, and has been employed considerably for the welding of bonds on street car rails. "It is interesting to note here the difference in practice between Great Britain and the United States," says Mr. H. A. Hornor, in a recent paper presented before the American Institute of Electrical Engineers on the subject of electric welding of ships. Mr. Hornor is a member of the Electric Welding Committee appointed by the Emergency Fleet Corporation. As he has pointed out—"Great Britain, knowing little or nothing about spot welding, had the practise and application of arc welding well under way, while conversely American engineers, on the other hand, had highly developed spot welding, even to the point where elaborate welding machines for this class of work performed their task automatically day after day, making successful new, very little having been publish in connection with it. The accompanying diagrams, figures one and two, show the two different processes of electric ship welding in a clear manner. To produce a spot weld, two heavy copper electrodes, water cooled in the heaviest machines, are placed on opposite sides of the material to be welded together, such as two steel plates. The joint is a lap joint, and machines are now available that will make two and more spot welds at one time. The details of the operation, which requires but a few seconds for each weld, are as follows:

The electrodes are brought into contact with the material to be joined, and current is supplied sufficient to give the required heat. Pressure is then applied; the current and pressure are then removed—the spot weld is then complete, and is usually as strong as the base metal which has been welded. The spot weld operator has a perfect indication of making a good spot weld by the use of a button placed under the electrode, and by observing it he knows exactly the proper timing of the operation. There is therefore no question as to a good, poor or indifferent spot weld.

Arc welding, which gives much promise of being rapidly adopted in steel shipbuilding at an early date, is carried out in the following manner: One side of the electric circuit is connected, as Fig. 2 shows, to the material to be welded, the shank material (Continued on page 572)
New Yankee War Inventions

By H. WINFIELD SECOR

WARTIME inventing has become more or less a profitable game in the past few years, and of late the electrical world of America has busied themselves in perfecting new schemes with which to overcome the Teutonic armament of the modern war. No less interesting of these patents which have been taken out are herewith described and illustrated.

The first invention is that of an electrically operated machine gun. This is a very interesting scheme indeed. Where a source of electric current is available, such as from a storage battery or from feed wires carried up to the front line trenches, this electric machine gun should prove of considerable utility. It has a detachable drive for the belt containing the cartridges and the firing pin mechanism is also positively controlled by the electric motor actuating the spring belt. The machine gun is fitted with a safety switch, which is connected in series with another switch mounted within the rear hand-grip as described. An illustration shows the cartridge belt is provided on its underside with a series of teeth adapted to mesh with the teeth of the gear wheel driving the lower wall of the chamber, and projecting upward into the same, so as to fit into the teeth formed in the belt. The belt is designed to be made in a number of sections, or it may be made in one continuous length with its ends detachably connected together when not in use. A bucket or other storage vessel to accommodate the tubular containers secured to the belt.

In operating this electrically machine gun the gunner simply grasps the hand-grip, after having closed the safety switch. The electric motor then starts up, causing the cartridge belt to move, and the cartridges are brought one at a time into the firing chamber. During the adjusting of the cartridge in the chamber the firing pin is thrown back, and the next instant a powerful spring throws the firing pin forward, striking the closed end of the cartridge, exploding it. This action is rapidly repeated, and a thousand or more cartridges fired per minute. A patent on this machine gun was issued to Louis M. McManus of Houston, Texas.

A second electrical military scheme was recently patented by Colonel Willis P. Coleman of the United States Army, and appertains to improvements for use in connection with the instruction of recruits, and particularly rifle marksmen, especially with regard to the proper method of holding the rifle and pulling the trigger without distorting the line of fire. As Coleman states the case—"It is necessary to hold the rifle in a vise-like grip during the operation of squeezing the trigger. The same time is to shoot a military rifle with any degree of accuracy." To bring the recruit to the realization of the necessity for the "hold and squeeze" is the most difficult part of the instruction, says the inventor. Here-tofore there has been no satisfactory method of concentrating on this particular part of the recruit's instruction.

The invention here illustrated provides a very simple scheme for overcoming this difficulty quite effectively. The recruit is nothing more than a dry battery or two, a small electric bell of the common garden variety, and a metal contact mounted on an adjustable board. The invention also supports a miniature target, all of which is arranged in the manner depicted by our artist. In practise the rifleman has to hold the piece so that the electrode-pin projects a short way inside the barrel and which will abrade him while he goes through the movement of loading and pulling the trigger. He must be able to pull the trigger without strain on the receiver or the instrument without moving the gun barrel sufficiently to bring it in contact with the central axis of the ring. No bullets are used in this maneuver of course. The invention is of wide application and extremely simple to adopt, and is, moreover, well-suited to training riflemen for shooting in any position, either prone, kneeling or standing.

A third invention on which Mr. George Fleming of Princeton, Texas, has taken out a patent, is that of an electrical shot-gun. The object of the invention, so states the patent, is to use a piece of wire which will close an electric circuit and immediately upon contact with the shell, to create a spark for igniting a combustible fluid or material which is mixed with the stock of the gun. By means of an insulated trigger and the necessary contact plates an electrical circuit is closed thru the cartridge or shell whenever the trigger is pulled. The shell is preferably adapted to contain powder, gas, or any other suitable combustible fluid. A spring-loaded projectile is to be shot from a barrel of the gun. The shell has a spark-plug mounted therein, so that contact of the trigger with this spark-plug will close the electrical circuit, and cause the contents of the shell to be ignited, and thus project the bullet out thru the barrel. Normally, a spring holds the trigger out of engagement and out of contact. For certain classes of shells, particularly small gas shells and the like, this idea is well adapted.

An Electro-Gasoline Cannon is illustrated in the fourth figure. This cannon or gun is intended to hurl forth projectiles by means of the same force as that employed in the automobile engine cylinder, i.e., by the explosive force produced when a gaseous vapor, such as that composed of gaseous line and air, is suddenly exploded by an electric spark. Thus no powder is necessary with such a gun. As the diagram and illustration show, the cannon is loaded thru a sliding breech-block in which the shell is placed. The gasoline and air mixture is obtained by means of a vaporizer, built on the principle of a carburetor, and this mixture is injected into the chamber back of the shell by means of a force pump. This is necessary to compress the mixture, and it is ignited by means of an electric spark produced by means of a spark coil and battery. The inventors, John Anthony and W. S. Bradford of Haynes, Arkansas, claim that perfect control of the fire is readily attained by the use of their gun, simply by variation of the force pump. They also point out that a crew can fire such a gun with little danger from explosions and that the cost of operating a gun of this type is said to be much less than the cost of operating a gun from which the projectiles are fired chemically. It may be interesting to our readers to know that a similar gun has, to our best knowledge, been used successfully in France, and also there has recently been developed a machine gun of this type which can fire three thousand shots per minute.

When the birdmen soar to lofty altitudes in the comparatively cold weather of mid-winter, or when the shooting season is over, the aviator is thrown upon the resources created by the cold. As a particularly effectual, electrically warmed aviator's shoe has been invented by William L. Lillard of Irvington, N. J. Mr. Lillard makes use of storage battery or other source of electric current, and his shoe is particularly useful for all those who may be exposed to extremely cold weather, including aviators, drivers of street cars, automobilists, etc. His scheme is particularly interesting in that the inner sole containing the heating element or grid may be adapted to any footwear, whenever desired.

An electric insole is used in both shoes, and electric conductors extend thru the heel of the shoe and thru the leather pocket attached to the outside of the shoe at the rear, connect with a storage battery or other source of electric current. It is thus evident that the electrical contacts in the heel and the sleeve covering the conductors leading up from the heel, may be quickly attached to any regular footwear, whether they be shoes or boots. Electrically heated helmets and gloves have also been very successfully by the Allied forces.

The sixth idea is a suggestion for naval and marine engineers, in the form of a quickly collapsible net to be used as a protection on ships against torpedo attacks. As the illustration herewith shows, the inventor, Mr. John Wosinski of Detroit, Mich., provides for a series of telescopic tubular superstructures which can be rigidly supported about the vessel when necessary. These arms may be quickly extended by the means of compresst air, by a hand-operated gear, or, better yet, by means of an electric motor. Each telescopic boom is supported by cables from the masthead and is able to sustain the weight of the net and floats. It is just possible that this idea may work out and be made available for the purposes for which it is intended. The net protector for ships, you know, is taboo in all naval discussions on torpedo defense, notwithstanding the fact that English warships have used them with success many times. Therefore, it is possible that Mr. Wosinski's invention may find acceptance in shipping circles in the event of the general objection to these torpedo nets heretofore having been that they reduced the speed of the ship and otherwise handicapped the movements of the vessel.

One of these fine nights "Kaiser Billiam" and the "Clown Prince" will be highly surprised when their headquarters and perhaps the rest of the family castles are bombarded by a gigantic flock of aerial torpedo bombers, of the type invented by a Neb-ras-ca genius, S. H. Benson. This aerial torpedo is devised so simply that the men on the ground can automatically drop a shower of bombs or other explosive missiles at predetermined points. By the use of a clever arrangement of trap doors in the shell of the torpedo and their releasing mechanism, the doors may be caused to open one after the other, as desired.

THE ONE-MAN TANK

(For Description See Opposite Page)
Tanks Uproot Wire Entanglements

By H. Gernsback

O NE of the most formidable barriers to the advance of the modern tank is the modern barbed wire entanglement. As is well known, it is almost impossible to charging infantry to move over the interminable entanglement once the latter is equipped with barbed wire. First of all, the advancing men are ready targets for the enemy, and once they come up close to the barbed wire, there is no way of getting over without the enemy spotting the men, when they can be easily picked off by means of the enemy’s rifle fire. In the past, many schemes have been suggested and are in operation, to either clear the barbed wire or else to destroy it. Perhaps the most efficient is the modern barage which levels and shatters to the ground all entanglements, blowing them to atoms, and the cable. The basic method is that the enemy’s entangled forces are sent out holding the ground to be emplaced, if any. After our steel wire has been shot over the barbed wire, all that is necessary for our men to do is to pull the wire to where they need it. Depicting in illustration, which tank may be some considerable distance behind our lines at any point which is best suited for the requirements at the moment. When all lines are made fast, it is necessary for the tank to start moving backward, when a considerable section of the barbed wire entanglement will be blown uprooted and pulled out of the way. The entire tangled mass of poles and barbed wire wreckage can then be pulled somewhere to the rear, where it is one of the most baffling problems of modern warfare. The writer wishes to advance an idea which has none of the objections cited above, while at the same time no new ma-

vance thru the open gap. The enemy will at most have a few minutes notification, which will not be sufficient to call in his reserves. One way to see that the advantage of this idea lies in the fact that a wide breach can be made at extreme expense to human life, for it is obvious that no human being need be near the barbed wire, unless, of course, volunteers should elect to place the grapple cables into the barbed wire by hand during the night, thus even dispelling with trench mortars. This can be done by sending out the men in no-man’s-land during the night to fasten the lines to the barbed wires. There are, of course, many other variations to this scheme which will immediately suggest themselves to the men in charge of this work at the front and who are best qualified to handle such matters.

Three Views Depicting a Novel Idea How to Uproot Barbed Wire Entanglements. Fig. 1 Shows Thin Wire Cables to the End of which Any Number of Hooks or Grapples, the Cables Being Shot Over the Entanglement by Trench Mortars as Shown. Fig. 2 Shows the Other End of the Wire Cable Attached to a Tank By Our Men. Fig. 3 Shows the Tank Uprooting the Barbed Wire Entanglements, the Hooks or Grapples at the Other End Holding the Cables Fast to Entanglement.

centrate reserves of infantry behind the attacked area, thus defeating the object gained by destroying the entanglements. Another favorite method originated by the Allies to shoot tanks run over the entanglements, crushing poles and wire to the ground, but again this method gives notice to the enemy, and while not as much as if the harrage were used, still notice is given. Also one tank or even fifty tanks cannot break down a large area of wire, for it stands to reason that each tank can only crush down an area equal to the width of the tank itself, which usually is not more than ten to fifteen feet wide.

Recently a Yankee colonel devised an original method whereby use was made of ordinary chicken netting interspersed with thin steel rods. A number of such wire rolls are arranged over the entanglement and the soldiers found little trouble in walking over this improvised bridge, but, of course, many casualties resulted by the Huns picking off the Americans with gun or rifle shot. All the methods cited above have one great objection, and that is that they leave the barbed wire on the ground in some form or other, and even if the poles and barbed wire have been crushed down, they still make very unpleasant walking as may be readily understood.

After a number of wires, spaced a foot a part, have thus been shot over the entanglement, not leave their trenches and attack the free end of the wire, as shown in our illustration, which tank may be some considerable distance behind our lines at any point which is best suited for the requirements at the moment. When all lines are made fast, it is necessary for the tank to start moving backward, when a considerable section of the barbed wire entanglement will be blown uprooted and pulled out of the way. The entire tangled mass of poles and barbed wire wreckage can then be pulled somewhere to the rear, where it is out of the way and will not harm our advancing infantry. It goes without saying that by using a number of tanks and by shooting over a sufficient amount of lines, almost any section of barbed wire can be cleared in this manner. This system would work, of course, where there is a double, triple, or even quadruple line of barbed wire entanglements, one behind the other. In this case, all our men have to do is to grapple the nearest line facing the enemy, and once our tanks begin pulling, the first line of entanglements will invariably become enmeshed with the second, third and fourth line, and uproot them all. It is merely a problem of having a big enough tank or tanks with heavy enough wire cable and grapples.

It also goes without saying that the tank which we have illustrated can be replaced by either heavy railroad track, or other wise compound hand tackles (chain blocks), if it is not advisable to use either tanks or automobiles.

In order to so not to give the enemy any information as to what is coming, the trench mortars can be fired in the evening or early morning, and the object can be successfully camouflaged by sending over ordinary trench bombs at intervals. Thus the enemy will have no notice of what is happening, and will take the firing from the trench mortars to be nothing more than the usual daily trench bomb bombardment. Then at dawn, about half an hour preceding the attack, the tanks can get busy uprooting the barbed wire entanglements, making a wide breach in the defensive system, and within a few minutes after thus clearing an opening, our infantry can ad-

President’s reply to German flashed by radio from Arlington.

President Wilson’s reply to Germany on October 22nd was sent broadcast to the world from the Arlington naval radio towers on the night of October 24th, after the official text had been put on the cables. It was picked up directly by the German station at Nauen, it was undoubtedly relayed from other points in Europe in time to reach Berlin in the morning.
Preserving Organic Substances by the Use of X-Rays

The apparatus here illustrated was recently developed for the purpose of utterly destroying insects or other animal life that would tend to destroy perishable articles, such as tobacco, certain foods, etc., or else to sterilize and prevent further propagation of the species, and also to destroy any eggs that the insects have already laid.

In certain instances, such as in the treatment of furs, woolen articles or feathers, it is desirable to destroy the moths or other destructive insects before they can do the damage. With other perishable articles, such as grains, the few weevils or other insects that may be found initially in the grain will do little damage to the grain, provided their powers of reproduction are annihilated or destroyed, and further that the eggs already laid be sterilized.

Again it is well known that tripe, which is infected raw pork, are in themselves harmless to human life; but that the second generation, when bred in the human system after eating raw pork, becomes very dangerous to human life. Therefore, in the case of the raw pork or of the grain, it is only necessary to destroy the fertility of the original insect, to a large measure prevent any material injury from the presence of such insect. Therefore, a Florida inventor, Mr. David Collins Gillett, devised the special X-ray "oven" here shown.

Mr. Gillett has provided a number of novel electrical features in working out this idea to the best advantage, and for one thing he greatly reduces the length of time required to thoroughly sterilize such articles, by providing a battery of powerful Coolidge type X-ray bulbs on either side of the oven. The compartment into which the cars containing the materials are rolled is partitioned off with wood or non-metallic sheeting. The outer wall of the X-ray cabinet is composed of wood or other suitable material, and the entire inside surface of the outer wall, including roof and doors, are lined with sheet lead, about one-eighth inch thick, to prevent the X-rays from passing thru the walls and exerting deleterious effects on the attendants. Special connecting racks are provided, so that the batteries of X-ray bulbs can be quickly replaced or reconnected and exchanged at any time. A milliamperemeter is provided for each battery of bulbs which registers the amount of high tension current passing thru them.

An electric motor connected to a high efficiency air blower on top of the cabinet craters a strong draft of air, which passes thru the two air compartments placed against the outer walls and inside of each X-ray tube compartment in the manner shown. Opposite each X-ray tube there is a shunt switchboard, with the usual ammeter and voltmeter, necessary switches, circuit-breaker, etc. Two safety switches are provided on the door frames, so that as the door is closed, as shown, the shunt circuit connected to the circuit-breaker on the switchboard will be automatically broken. A time switch, which may be set for any given length of time, or for any given number of applications, will open the circuit of the appliances, thus preventing overheating of the apparatus.

New "X-Ray Oven" for Treating Tobacco, Meats, Besides Other Foods and Substances Liable to Contain Animal Life or the Eggs Laid by Insects, thus Sterilizing Them and Effectually Preventing their Propagation.

A motor provided a pair of nozzles thru which this air can escape in a direct stream on to the tubes, thus helping to keep them cool. The X-raying compartment is made with a high-potential, high-tension transformer for operating the bulbs, and develops a potential of about one-hundred-thousand volts at the secondary. The low-potential, filament heating current for the bulbs is provided by two step-down transformers. All of the apparatus is readily controlled from the switchboard on the exterior of the cabinet.

SAW "SPY" SIGNALS IN THE HUDSON.

Following the military order forbidding "suspicious lights and signaling" along the Hudson, the first observed instance of signaling was reported recently by Captain Franic Crossman of the Hastings-on-the-Hudson Home Guards. Captain Crossman said that his men reported seeing signaling between a motor launch and a post on the top of Hook Mountain, back at 9:30 p.m. one evening, again at 11:30, and the last time at 3 o'clock in the morning. Capt. Crossman said that at 3 o'clock one of his guards observed a low-built launch, of the racer type, slow down off Hook Mountain and, using a light hung at the masthead, flash a code message. The blinking of the lantern was kept up for about five minutes, and then three short flashes winked from the mountain top.

The guardsmen, warned by the two earlier visitations, had a launch ready to go out to the suspicious craft. Before the guard boat could get within halting distance of the stranger, however, the latter sped downstream toward New York.

Members of the Home Guard pointed out that it is from the top of Hiethoven, in the Ramapo's, back of Hook Mountain, Revolutionary officers thru spy-glasses used to watch the movements of the British in Long Island Sound as far west as Nantucket. Guardsmen said that a powerful signal on Hiethoven could be caught by a U-boat lying off Nantucket. Home Guardsmen said that from Hook Mountain spies armed with strong fieldglasses could sweep Camp Meritt, near Cresskill, N. J.

It is Reported that "Spy" Flash Signals Were Observed at Hastings-on-the-Hudson, the Signals Being Flashed from a Launch in the River Up to Hook Mountain. How Easily these Signals Could be Relayed to Mount Hiethoven, and Thence to a U-Boat in Long Island Sound is Made Evident.
Huge Electric Toys

These photographs show the unique electrical display of toys made by a Seattle, Wash., toy concern. The immensity of the toy figures made the public gasp for breath. fantastically colored in typical "monkey pose," so familiar to everyone. The huge moving figure is mounted in a shadow box, which produces a most spectacular lighting effect at night. Behind the black background is concealed the intricate electrical mechanism which makes the monkey's head, arms and leg move, and the contented smile on the monkey's face shows his satisfaction at creating such a disturbance among the children as well as the grown-ups of the city. The idea is an original conception, nothing of its kind ever having been attempted before, and the oddity, immensity and originality of the huge moving figure caused widespread notice and created a petulant grin to be seen on the scores of faces which continually watched the fantastic movements of the clever monkey.

The electrically lighted jumping jack was 15 feet high. The daily uniformed General was 22 feet, while the Private stood 19 feet in height. Looks like "Papa Billiard" abiding to the "Clown Prince."

THE AERIAL MONOFLIER IN THE AUGUST "E. E." WORKS!

Our readers will undoubtedly remember with interest the proposed "Aerial Monoflier of the Future," illustrated and described in color and diagram in the August, 1918, issue of this journal. Many letters of criticism were received, saying that this apparently wild dream was a real impossibility and would not work. Some of the writers objected to the support of such a large car on top of a cable by means of a stabilizing gyroscope, claiming that a gyroscope capable of doing this would have to be larger than the car itself, etc., etc.

So, all hail the advent of a real monoflier, shown in the accompanying photograph! We just recently came across this toy monoflier, and purchased one to try it out. It worked admirably and would run along a cable or string in fine shape. A small, lead wheel gyro, about two and one-half inches in diameter, by one-quarter inch thick, is geared to one of the two traction wheels under the car, so that when this wheel is spun by drawing the car across the floor, the gyro spins at high speed and the car takes on all the features of the gyroscope itself, i.e., it manifests a remarkable stabilizing power in the vertical plane. To give an idea of the powerful stabilizing effect of this small but rapidly spinning gyro, it may be mentioned that the metal car measures nine and one-half inches over all, stands four inches from top to bottom and measures two and one-quarter inches in width.

Of course, it is a simple matter to arrange a car of this type with an electric motor, supplying the necessary current to the motor thru a trolley arrangement on top of the car. Also a similar sized car was tried out with an electric motor fitted into it and driving two propellers, in exactly the same manner as that proposed for the aerial monoflier described in the August issue, and the car rode up an inclined cable very successfully. "Truly, it may be said that "science moves in mysterious ways, its wonders to perform"—to paraphrase the famous biblical passage."

NEXT! WOMEN ELECTRIC WELDERS.

Women electric welders are the latest in shipyard news. Hog Island won the honors on the one hand and three girls who are making good at their new work, on the other. There's riveting, rigging, bossing, and a lot of others, and we'll see how much longer men will hold out against willing women.

Several weeks ago Miss Sarah A. Erwin applied at Hog Island for a job, and they told her they had a chance for her in the electric welding department. The novelty of it was pictured so alluringly that Miss Erwin became the first electric welder of her sex in the world, so far as is known. Not long afterward Miss Anna Kennewie applied for a try at the new work, and she and Miss Erwin both developed skill so rapidly in the training school that they were soon turned over to the production department. Number three is Miss Mary Dunn, also of Philadelphia, who is still in training.

JAPAN TO HAVE ATMOSPHERIC NITROGEN.

According to a bill past by the last diet the government of Japan has decided to establish a laboratory for the study of the fixation of atmospheric nitrogen. The demand of ammonia for fertilizer amounts to nearly 20,000,000 yen each year, and up to now this has been supplied solely by import. It is hoped to make this a local industry in the near future.
ELECTRIC XMAS SUGGESTIONS

Submarine Chaser Model. It is Available in Electric or Spring Motor Drive. A Present That Will Tickle the Sides Chasing Rheumatic Pains Away.

Experimental Chemistry for the Boys. This Complete Outfit Gives a Good Education in Chemistry. Instruction Book of 100 Experiments and Tables Tells How.

A Trans-Atlantic 10,000 Horsepower Aerial Liner

By W. EDUARD HAEUSLLER

The Palace Trans-Atlantic Aerial Liner "Etheric" Nearing New York Harbor. Sandy Hook Lies to the Right of the Picture. Equipped with a Powerful 10,000 Horsepower Engine Plant, Radio-telegraphy, Aerial Sounding Signals and Sleeping and Eating Accommodations, This Wonderful Craft Makes the Trip from London to New York, a distance of 3,456 Miles, in the Remarkably Short Time of 31 Hours. Steamships Cannot Much Improve on a Four-day Trip Across the Atlantic, No Matter How Powerful the Engines with Which the Vessel Might Be Fitted. A Speed of 100 Miles Per Hour Is Common Nowadays for Airplanes.

In the very near future one may expect to see such a placard posted in a conspicuous place and past with only casual interest, as it will have become commonplace. Likewise the daily appearance of a monstrous aerial flier such as the "Etheric" would not cause excitement—perhaps just a slight interest as to her passenger list.

"All aboard for London!"—Then amid the roar of the big siren and that of the six gigantic motors, aggregating in all some ten thousand horsepower, the noise of which is deafening, the last passenger steps aboard, the small wooden stairs are removed, and the gigantic machine starts to rise rapidly into the air, bound from New York to Harbor Grace, Newfoundland—one thousand one hundred and forty miles distant, the first lap of her trans-Atlantic journey.

The city beneath appears to be dropping away from under you, the buildings and tall skyscrapers become a mere jumble of varicolored squares, interwoven by a mass of threads resembling a net, which in reality, are streets, and the "flies" that you perceive moving about in them are the rushing masses of New York's busy people. Your attention is drawn to a small winding thread, and when you follow it with your eye, you notice that it extends and disappears into the horizon. This, you are informed, is the Hudson River. After the flier has gone several thousand feet higher, you become interested in the apparent widening of the circle of land and water within the horizon. This is due to the height, for as our altitude becomes greater, so also does the area of land beneath you increase in size. This holds true to a certain altitude, above this limit of height the expanse of the horizon again decreases in diameter. You chat for a few moments with a fellow passenger, when of a sudden, you notice the lack of turmoil and the noise of the city, which has been replaced by a noticeable and complete calm.

Looking over the rail you are surprised to find that the flier has made remarkable progress and is over the restless waves of the sea. The next to attract your attention is the announcement that a landing at Newfoundland is to be made in a short while, and that a period of twenty minutes will be allowed, during which time you can again become accustomed to walking on "terra firma." This time is utilized by the crew to provide ample fuel and provisions for the flight over the 1,940 mile stretch of ocean. The landing station at Newfoundland is an imposing structure rising some five hundred feet in the air. There are two large express elevators for conveying the passengers to and from the aerial liners and the streets below. Use is made of the new magnetic landing scheme and a "whirling disc" starting device, which appeared in a previous issue of this magazine.

After the necessary fuel and provisions have been carefully stowed aboard, the engines are started again and the plane rapidly rises into the air; the sensation and observations are identical with the ones experienced upon leaving New York. The pilot of the "Etheric" heads her straight up into a strata of air about 2,000 feet above the surface of the sea. A noticeable decrease in temperature is the result and a very light-headed feeling ensues. Looking off to the east, that is, straight ahead, a very dark and menacing bank of clouds is observed. Apprehension is felt, as this black appearance will shortly prove to be a severe electrical storm. But the passengers may feel reassured, as their safety has
been provided for by the equipment of the "Etheric" in the form of lightening rods. These rods extend on all four corners of the ship and ground is obtained by the dropping of a copper wire to a distance of about 150 feet from the bottom of the plane. Upon the extremity of this wire is placed a torpedo-shaped steel "fish." Should the misfortune occur that the "Etheric" were to be struck by lightning, the lightning would be extinguished, but still from the protruding rods down thru the insulated wire and dissipated into the air below the machine by means of the "discharge在外的".

Our pilot, with expert skill, starts the gigantic airplane on a rather sharp angle and the powerful motors respond quickly, carrying it to a height of 12,000 feet. At this height we are absolutely safe from any danger whatever that might have been in store for us from the approaching thunderstorm. The speed of the plane heading directly into the tempestuous area carries us above it in a very few minutes. The roll of the thunder is ear-splitting; we fail, however, to see any lightning discharges as we are above the storm; and therein our feeling of insecurity soon passes off.

By referring to the chart that is placed amidship on either side of the cabin deck, we discover that we have traveled some 600 miles since leaving Harbor Grace. A fellow passenger is heard to remark, "I feel the beginning to feel rather chilly. A plane-hand, over-hearing the remark, informs me that the heat in the cabin has been turned on and he will find comfort below. We are skeptical — for who ever heard of heat in an airplane? Being Americans, we are naturally inquisitive and our curiosity got the better of us, so we descend the stairs in order to find out for ourselves if what we were told is true or was mentioned to give us a "psychological cushion." Going downstairs we notice a perceptible increase in temperature and a feeling of well being once more. After climbing to the upper floor, we are conducted to the kitchenette, where we are offered aperitifs. From the corners of our stomachs, an electric gong starts to ring vigorously and as we have heretofore learned, it is the evening signal that "dinner is served."

The food is very good, and the fare is wholesome and satisfying. It consists mostly of canned goods, due to the lack of room and the ever-present need for lightening the cargo. However, it suffices to allay our appetites until we shall make a landing at Queenston and then we can partake of good old Irish "spuds." Soon night falls and we retire in our tiny cabins, where we are soon lulled asleep by the musical vibration of the "Etheric's" motors. Our sleep is untroubled.

About noon next day the summer sun brings out the highlands of Ireland in bold relief, and as we drop lower, altitude in order to affect a landing, we begin to realize that the populace in the cities of the country which we are to visit must necessarily be perceiving in this sweltering heat. We are made very comfortable by the thoughtfulness of the steward, who in the evening, in the lounge time, have put out for our comfort, even to the turning on of the four electric fans in the lounging room.

Despite the intense heat (note rapid change in temperature), we are all crowding to the rail in order to see where and how we are going to again come back to Mother Earth. Only an experienced question is very quickly answered when the machine comes to rest on a landing stage, an exact duplicate of the one we left at Newfoundland.

There are two things that attract our attention and in which this place differs from the Harbor Grace terminus—one of which is a slightly smaller size airship, built practically on the same lines as our ocean-going planes which is marked in very large letters designating that it will carry us to London if such is our intention and destination. The second object of interest is a large observation balloon suspended at an elevation of 1,000 feet above us; in which we can faintly see two men waving their periscopes. This special equipment is to show what type of balloon is for, we are given the information that this is the "meteorological station," operated by the Trans-Atlantic Airplane Company and by means of which the various nautical and air observations are determined and reported. Under this heading we are told that the temperature, visibility, time, tide and kindred other computations are made.

Upon this we are overhauled by a crowd of curious peasants, hucksters and market people. After finally disengaging ourselves from this human net, we arrive at a small town. One of the squares consists of an Irish jaunting cart drawn by a one-mule-power animal, "Mike" by name, who looks at us in his lazy way and seems to say, "You come over, up in the air, and you will again go up in the air trying to make me pull you and all of your infernal luggage." Climbing into the cart, with some feeling of insecurity, we finally arrange ourselves comfortably and our hackman starts to bawl out at his "hony" mule, and once more we are off on our way and about to visit the splendors and beauties of the picturesque Irish landscapes.

This story of a trans-Atlantic trip is not an idle fancy, but a logical forecast of the remarkable progress in aviation, the materialization of which will be found not many years hence.

The proposed mammoth Aeriel Liner here pictured will be constructed along the following specifications, according to logical figures which have been past upon by competent authorities. It will have a wing span of four hundred and twenty feet, a fuselage length of two hundred and ten feet, and a height of ninety feet from upper to lower planes. The planes, three in number, will extend horizontally from the hull of the ship to a width of two hundred and ten feet on either side.

The hull, containing the passenger compartments, is built on a stream-line basis, resembling that of a sulfur-bottomed whale, and is arranged to accommodate eighty-five persons, besides a crew of fifteen men, a total of fifteen thousand pounds of cargo, and carrying seven thousand pounds for support, he will be able to fly for the 18 hours' run; seventeen hundred pounds of the service capacity would be available for baggage.

The motive power is derived from six high-powered gasoline motors. The three motors situated on the upper deck and the two on the lower tier of the planes are of sixty-five hundred horsepower each. The central motor situated in the forward section of the hull is of two thousand horsepower; all the stupendous total of ten thousand horsepower, weighing in the neighborhood of twenty thousand pounds.* The horizontal and vertical stabilizers are of a design that takes advantage of the updraft of the machine, as are the rudder and elevator.

The upper side of the wings will be designed to take advantage of the upward suction. It might be well to state that 66 per cent of the lifting power is due to the suction on the upper surface of the wing panel, while only 33 per cent is credited to an actual pressure of air on the under surface. The lifting capacity of these three planes will be 1,000 per cent for the upper, 20 per cent for the middle, and 35 per cent for the lower plane. Figuring their angles to be 4°, the lifters will be capable of 1,400 pounds to

(Continued on page 594)

*The total gross weight will be 120,000 lbs., or 60 tons, and a useful load of 22,000 lbs., or 11 tons.
Electrical Testing Engineers Made to Order

By C. M. RIPLEY, of the General Electric Co.

CAN you imagine the delight in the heart of a young man when he goes to his post of duty on a battleship, cruiser, destroyer or submarine, in Uncle Sam's navy, and finds that he has charge of some machines, similar to those which he himself tested and adjusted in his student days? 100 men in a factory—in all of these activities—he must be a 100 per cent man.

But work in the Navy and in the Army is not the only kind of work that Electrical Engineers are doing and will continue to do for centuries to come—for electricity is useful in peace as well as in war. In fact electricity is necessary to American industry, and the wider and wider America uses electricity in the future, just so much more efficient will she be in battling for the markets of the world.

Men from all over the world meet on common ground in the Testing Department of this electrical concern—a department which occupies 72,000 sq. ft. of space. This area in downtown New York would cover nearly 15 city blocks, each the size of that occupied by the Equitable Bldg., which is bounded by Broadway, Nassau, Cedar and Pine streets. This space is 29 per cent greater than the entire rentable area of the Woolworth Bldg.

One reason why the Testing Department is the best department for a young man to start his career in, is because it takes him into so many different buildings and permits him to handle so many different types of apparatus. Hence, it is ideal for developing his knowledge of all types of electrical machinery.

The apparatus is tested where it is manufactured. The rough castings are received at one end of the building, machined, assembled at about the middle of the building, are then tested, and at the farther end of the building they are painted, boxed and loaded on the railroad cars to be carried later on mule back into the Andes mountains, on dog sleds into the heart of the Yukon, hauled by mules or by human carriers in China or by elephants in India.

Would you believe it possible that this concern has set aside and reserved merely for testing purposes, 250,000 k.v.a. of electrical apparatus? This statement is the result of a careful census and a conservative one, since it does not include any of the power stations—a certain portion of which are used for testing purposes.

At one of the plants the power station has only 1/10 the capacity of the Testing Department equipment. The total capacity of apparatus reserved for testing in each factory is greater than the capacity of its power supply. This situation is largely due to the "feeding back" method by which two motors, both under test, are used for testing each other—one running as a generator and the other as a motor. This saves floor space, saves power and lessens the generating capacity. The feeding back method permits testing to be done on an enormous scale with the use of a comparatively small amount of coal, as the machines being (Continued on page 590)
A NEW GAS-FILLED LAMP AND SHADE IN ONE.

The accompanying illustration shows a unique ornamental gas-filled lamp recently developed by a large lamp concern.

It is claimed that this lamp produces an indirect non-glare light which will not injure the eyes. The lamp is interesting in that it combines an ordinary gas-filled bulb with an ornamental lamp shade. The lamp, known as the "Liberty," is made of plain white glass with ornamental decorations in green, gold, blue and other shades that will harmonize with chandeliers or room decorations.

A NOVEL ELECTRIC WINDSHIELD CLEANER.

Altho simple in construction and easily attached the new electric windshield cleaner illustrated, manufactured by a Philadelphia concern, is attracting considerable attention in scientific circles, having been exhibited for the first time only recently.

A plate-glass disc, set in the windshield of any make of motor car or truck, is whirled at 2,000 r.p.m. on fine ball bearings by a tiny electric motor, the centrifugal force throwing off rain, snow, sleet, mist or dust, thereby keeping the vision area clear in every kind of weather.

ELECTRICAL EXPERIMENTER

The small motor is driven by current from the car's regular motor, the makers claiming that its operation costs less than that of a single headlight. Perfect balance and scientific precision of the instrument, it is explained, makes the high speed possible with minimum power consumption, there being no frictional wear and tear. A push button, installed in a convenient place on the regular instrument board, controls the current.

No repairs are necessary, it is claimed, the entire device requiring no cleaning or polishing. The motor is weather and rust-proof while the bearings are of a special type of fine alloy steel.

The diameter of the standard size plate-glass disc is seven inches. All parts, except the glass, are of white metal, heavily plated with nickel or black gloss.

Altho made especially for use on motor cars and trucks, the device also is adaptable for use on battleships, submarines and aeroplanes. While the standard size is seven inches, larger diameters are obtainable.

LACING SHOES BY ELECTRICITY.

By Frank C. Perkins.

The accompanying illustration shows a machine which performs with remarkable rapidity and perfect accuracy the operation of shoe lacing which, prior to its introduction, was purely a hand one and inaccurate. It is absolutely required wherever fine shoemaking is attempted to lace the shoes at the throat with thread prior to the lasting process. The demand for lacing with this machine has long been limited only by the number of operators who could be trained for this work, requiring as it does exceptional skill and experience to do even passable work.

It is pointed out that lacing with thread is practically the one method by which the eyelets and uppers of shoes can be protected from injury and which allows the upper to be drawn closely down to the last—considerations which are of the utmost importance in fine shoe making. The operation of the machine is very simple, all that is required of the operator being the bringing of the two sides of the shoe tops into position, so that the corresponding eyelets are back to back, and placing them over spindles on the machine.

A slight pressure of the foot lever starts the machine in operation and the thread is quickly past thru the eyelets and tied in a hard, unyielding knot, after which the properly laced upper is removed from the spindles, when the machine is ready to repeat the operation. A simple adjustment makes it possible to vary the location of the knot, so that uppers may be tied to allow any desired spread at the throat.

It is stated that as the stretch or the thread used is uniform, one or two simple tests are all that are necessary in regulating the placing of the knot to secure the desired result; and, once this is determined, the ma-
Turning Air Into Bread—Nitrates from the Air

By ROBERT H. MOULTON

If anyone came along and remarked offhand that air could be turned into bread, he would at once be considered a bit subject to confusion in lunacy. Nevertheless, this very thing is being done today, and what is more, Nature has been doing it very well for millions of years. The explanation is this: Nitrogen is drawn from the air and then converted into nitrates. Nitrate of lime is a rich plant food and when it is incorporated into the soil makes a wonderful fertilizer. The other natural deposits of nitrates are in Chili, South America, from which, up to the time of the present war, 1,800,000 tons were exported annually to fertilize the farms of the other parts of the world. But the Chilean nitrate deposits cannot be depended upon with certainty, even after peace shall have come. It has been calculated that the Chilean deposits will be dangerously reduced by 1923, and inside of a score of years the supply will be exhausted.

For these reasons the discovery of a practical method by which the inexhaustible supply of nitrogen in the atmosphere can be utilized, is of the greatest possible moment to the entire world.

To two Norwegian scientists, Professor Birkeland, of the University of Christiania, and Samuel Eyde, an engineer of the same city, is due the credit for discovering this method. They are now taking nitrogen from the air, solidifying it and preparing it for application to the soil. And, whereas the method of Nature requires an entire season to do this, the method of the two Norwegian scientists requires only a few days.

The plan in a nutshell is as follows: The air is drawn thru oxidation towers and is then forced thru electric arcs, where a terrific heat is maintained. The oxygen and carbon dioxide in the air are consumed, leaving the nitrogen. This is precipitated in the form of nitrous oxide. This nitrous oxide is then conveyed to immense porcelain towers 75 feet in height, where it is condensed and allowed to settle in vats of limestone. The chemical action then results in the production of nitrate of lime.

For several years a nitrogen making plant has been in operation near Rjukan, Norway, where 250,000 horsepower are drawn from the falls. Working day and night these quarter of a million water horses manufacture, out of the air, 200,000 tons of nitrat of lime per annum. But this describes the electric flames consisting of powerful arcs of light, which are used in the electric furnaces.

The formation of the flame occurs by an arc of the electric flame being formed between the points of the electrodes, which are close to each other. By this means a movable and flexible current is established in a highly magnetic field. The electric arc that has been formed moves on account of the magnetic field with great velocity parallel to the lines of force, and the electric arc's feet draw back from the points of the electrodes.

To regulate the current, an inductive resistance is used in series with the flame. With alternating current all the arcs are formed alternating in opposite directions and appear to the eye to be circular discs. This flame provides the powerful technical means for the oxidation of the nitrogen of the air.

The electrodes are thick copper tubing, thru which water is passed for cooling purposes. See photograph herewith. The chamber in which the flame burns is circular, of only a few centimeters width, and about three meters in height.

The interior of the furnaces is lined with fire-clay brick, thru the walls of which the air is admitted to the flame. The nitrogen formed in the flame escapes thru a channel made along the casing of the furnace, which, like the flame chamber, is furnished with fireproof bricks.

In order to supply the furnace with the amount of power desired, each coil is furnished with an induction coil, by means of which the power is regulated as required. The inductance coil serves, moreover, to keep the flame in the furnace steady and even while working.

The temperature in the flames is at the Rjukan plant 3,000 degrees Centigrade. The temperature of the escaping gases varies between 800 and 1,000 degrees. The furnaces are made of cast steel and iron, the middle of the furnace being in the form of a circular flame chamber. The electrodes are led radially into this flame chamber. By the aid of
centrifugal fans the air is brought into each furnace thru tubes from the basement. When the air in the flame chambers has been acted upon by the electric flame the nitrous gases formed pass out thru pipes, which convey the gas to steam boilers, in which the temperature, which was approximately 1,000 degrees Centigrade, is reduced. The gases pass on from the steam boilers thru an iron pipe into a cooling house, and complete the cooling begun in the steam boilers. Each cooler consists of a large number of aluminum tubes, over which cold water runs, while the hot gases pass thru them. In these tubes the temperature of the gas is considerably reduced. From the cooling chambers the gases pass to the oxidation tanks. See diagram in continuation.

The towers are vertical cylinders, lined with acid-proof stone. The object is to give the cooled gases a sufficient period of repose, in which time the oxidation of the nitrogen oxide may occur. The necessary amount of oxygen is present in ample quantity in the air which accompanies the gases from the furnaces. From the oxidation tanks the gases are led by blast engines into the absorption towers.

The towers are filled with broken quartz, which is affected neither by nitrous gases nor nitric acid, and thru them there is a continual trickle of water. The water absorbs the nitrous gas and when the liquid has become nitric acid of sufficient strength (30 per cent.) it is collected in cisterns, and from them again into vats filled with limestone.

There is considerable noise then, as the nitric acid displaces the carbonic acid of the limestone. The result of this is a watery solution of nitrat of lime. It is pumped into the vacuum evaporating apparatus, heated by steam from the boilers which are kept hot by drafts of fresh gas from the furnace. When evaporation is completed the solution contains 13 per cent. of nitrogen and it is passed into chambers where it is solidified into a hard crystalline mass. Later this is taken thru crushing machines, reduced to a coarse powder, and put into casks holding 100 kilos each. This powder is the finished nitrat of lime. The air has now been converted into fertilizer ready for application to the hungry soil. The U.S. Government is now preparing to erect powerful nitrogen fixation plants.

(Continued on page 502)

LADIES! WOULD YOU LIKE TO VISIT YOUR NEAR-BY ZOOLOGICAL PARK? PERHAPS YOU TIRE OF WALKING AROUND TO SEE THE VARIOUS LIONS, TIGERS AND POLAR BEARS, IN WHICH CASE, YOU CAN, IF VISITING THE BRONX ZOO IN NEW YORK CITY, FOLLOW THESE TWO LADIES IN ONE OF THE NEW ELECTRIC CHAIRS AVAILABLE FOR VISITORS AT THIS PARK.

LADIES! SEE THE ZOO FROM AN ELECTRIC ROLLING CHAIR.

Pleasure can now be mixt with knowledge at the New York Zoo by those who go there to study the animals. No more will it be necessary to walk miles upon miles to study all the exhibits on display in the greatest menagerie in America. Just get your electric roller chair—make believe you are the board-walk at Atlantic City—and see all that is worth seeing in Bronx Park. A twist of the hand lever and away you spin on your trip to see the lions, polar bears, giraffes, and monkeys. A storage battery concealed within the car body furnishes the electric current to actuate the motor which propels the vehicle. Electric headlights are provided for night travel, as well as an electric siren to warn pedestrians traffic.

WOMEN AS ELECTRICAL ENGINEERS.

The Rolin Chemical Company, with a plant at Charleston, W. Va., is hiring women to serve as electrical engineers because of their inability to secure men. Fifty-two will be employed.

A Belgian machine for digging canals will eat its way thru the ground at a rate of 100 yards an hour.

NAVAL CONSULTING BOARD CHANGES ADDRESS

Suitable space having been provided for the Naval Consulting Board in the new building of the Navy Department, at Washington, D. C., the preliminary examination of inventions, which heretofore has been conducted in the New York office, has been transferred to Washington, where it will be directed by Mr. David W. Brunton. All correspondences relating to inventions should be addressed as follows:

NAVAL CONSULTING BOARD
NAVY DEPARTMENT

THE TOTAL SOLAR ECLIPSE OF JUNE 8, 1918
By ISABEL M. LEWIS
Of the U. S. Naval Observatory

TOTAL eclipses of the sun and the advent of comets are two celestial happenings that have always been observed by mankind with the liveliest interest. If the advance of astronomical knowledge had accomplished nothing more than to free the nations of the world from the hysterical fear formerly aroused by these two phenomena, it would be worth all that it has cost.

Only two hundred years ago a total solar eclipse in England was predicted in a pamphlet, entitled "The Black Day or a Prospect of Doomday." Exemplified in the great and terrible Eclipse, which will happen on the 22nd of April, 1915! Predictions of total eclipses of the sun still continue to be issued in the form of pamphlets, but instead of direful prophecies they now contain carefully prepared information and enlarged maps of the region traversed by the path of totality to facilitate the successful observation of a phenomenon that is now considered to be of such scientific importance that expeditions from many nations have at times been sent thousands of miles to observe it.

It is now a matter of universal knowledge that eclipses of the sun occur when the moon passes directly between the sun and earth and temporarily conceals the sun from our view. Since it is only at the time of new moon that the moon can pass between the earth and sun, eclipses of the sun must always occur at new moon and when the earth can come between the sun and moon and cast its shadow over the moon. Since the earth is much larger than the moon its shadow is much larger than the moon's shadow and as a result the moon becomes entirely emersed in the earth's shadow during a total eclipse of the moon, while during a total eclipse of the sun, the moon's shadow just about reaches to the earth. In fact the apex of the moon's shadow cone comes between the earth's surface and its center in a total solar eclipse. There are times when the apex of the moon's shadow falls short of the earth's surface. Then an annular eclipse of the sun occurs. That is, the moon's disk just fails to cover the sun's bright disk, giving the effect of a bright ring or annulus of light surrounding the dark body of the moon, whence the name annular eclipse of the sun. So near is the apex of the moon's shadow to the earth's surface during eclipses of the sun that occasionally an eclipse may be annular in one part of its course and total in another, the apex just grazing portions of the earth's surface and totally falling on the earth at the most. The width of the shadow path then shrinks almost to zero. The average width of the path of total eclipse is about sixty miles and its length something like eight thousand miles. The greatest width attainable by any shadow path of the moon is one hundred and seventy miles and this can only occur under a most exceptional and favorable combination of circumstances.

The moon's shadow trails over the earth's surface in the form of a narrow band of great length. If earth and moon were stationary the shadow would appear as a small dark ellipse on the earth's surface, but owing to the motion of both bodies and chiefly to the earth's rotation on its axis the shadow sweeps over the earth in a long narrow strip bringing successively for a few brief moments the phenomenon of a total solar eclipse to all located within its path. The average duration of the total phase of an eclipse at any one point in the path is only three or four minutes. Under the most favorable combination of circumstances totality may last seven minutes and fifty-eight seconds and it varies in length from this value down to zero, according to the circumstances of the eclipse. When the apex of the shadow fails to touch the earth's surface, passing either above or below it, there may still be visible a small portion of the eclipsed sun, the magnitude depending upon the distance of the sun.

Can occur at no other time. On the other hand eclipses of the moon occur only at the time of full moon, for this is the only time

Diagram to Show Positions of Sun, S; Moon, M, and Earth, E, at the Time of Total Eclipses of the Sun and Moon. Every Year There Must Be at Least Two Eclipses of the Sun and There May Be as Many as Five. There Can Never Be More Than Three Eclipses of the Moon in a Year and Some Years There May Be None. The Greatest Number of Eclipses Solar and Lunar Combined That Can Occur in One Year Is Seven. Some of These Are Only Partial Eclipses.
central line of the shadow cone from the earth. Also whenever there is a total eclipse of the sun upon the earth's surface the partial phase is visible for hundreds of miles on either side of the central line of the shadow, the magnitude of the partial phase decreasing as the distance from the path of totality increases. Partial solar eclipses are quite common occurrences, but so narrow is the path of total eclipse that hundreds of years sometimes elapse before a certain town or district is visited by a total eclipse of the sun. Every total eclipse of the moon on the other hand is observable from the entire night side of the earth since the earth's shadow is so extensive that the moon passes entirely into it during the total phase. So it is that all of us have seen total eclipses of the moon, which unfortunately have little scientific value, while very few of us have had the good fortune to observe one of the most impressive scenes that nature affords, a total solar eclipse.

On the eighth of last June a narrow strip of territory within the United States lay in the path of the moon's shadow cone while the partial phase of the eclipse was visible to a greater or less extent over the entire North American Continent. The central path of the shadow cone first touched the earth near Japan. After crossing the Pacific Ocean in less than two and one-half hours, it reached the western coast of the United States at the mouth of the Columbia River in the afternoon, crossed diagonally across the country reaching Florida forty-seven minutes later and two minutes afterwards past the earth at sunset near the Bahamas. The frightful velocity with which the moon's shadow travels over the earth can be judged from the fact that it journeyed from Japan to Florida in a little over three hours. The longest duration of the total phase for any one point in its path was two minutes and twenty-three seconds. Within the United States the duration was even less, averaging about one and a half minutes. The width of the path in the United States averaged fifty miles. Short as was the duration of the totality of June 8th the eclipse was observed with great success by expeditions sent out from the leading observatories of the United States and, if the World War had not prevented, expeditions from many European nations would doubtless have traveled to the Western States to observe the phenomenon. As it was, many astronomers in our own country who had planned to observe the eclipse were unable to do so owing to the urgency of war work.

The Corona, from a Negative by Edison Pettit. Top Is North, Left East. The Two Large Prominences on the Eastern and Western Limbs Are 35,000 and 45,000 Miles High Respectively. The Corona Streamers Themselves Reach Hundreds of Thousands of Miles Above the Surface of the Sun. The Little White Circle on the Right Under the Head of the Sun Represents the Actual Size of the Earth. It Gives a Good Idea of the Immensity of the Prominences.

The Lick, Yerkes, Lowell, U. S. Naval and Mt. Wilson Solar Observatories sent expeditions to favorable locations near the central line, as well as a number of college observatories; nearly all of these expeditions obtained photographic and spectroscopic results of great value to science. Clouds brought suspense to practically all expeditions and to observers stationed at Denver, the largest of which is a shadow path, they brought a completely overcast sky and the keenest disappointment. At Goldendale, Washington, the Lick observers were kept in uncertainty until the last moment, but were rewarded by a surprising break in the clouds, perfect seeing, at the critical time and a number of valuable photographic plates. A number of eclipse parties at Matheson, Colo., met with exceptional success as did also the U. S. Naval Observatory expedition to Baker, Oregon. The Yerkes and Mt. Wilson Solar Observatory expeditions at Green River, Wyoming and the Lowell Observatory expedition near Syracuse, Kansas, were hampered, but by no means defeated, by clouds and some remarkably fine views of the eclipse were secured at these stations.

The most important feature of a total eclipse of the sun is, of course, the corona. It can be seen at no other time. It is now possible to study with the aid of suitable instruments, such as the coronagraph and spectrophotograph, all the complex features of the solar atmosphere with the exception of the coronal gas. However, if the outermost solar envelope. Its light is excessively faint and so is invisible to the human eye except when the moon acts as a screen for our eyes and permits us to glimpse the exquisite beauty and intricate form of the coronal rays and streamers for a few valuable moments. At such times photographs of the corona are obtained and records of its spectrum as well, for use in later careful investigation of the nature of the light and the causes for the peculiar changes or form of this strange appendage of the sun.

It has been found from studying and comparing a long series of photographs taken during different total solar eclipses that the form of the corona is extremely intricate and that it undergoes periodic changes that are associated in some unknown way with the period of sun spot frequency. When sun spots appear in greatest numbers on the solar surface the corona is very brilliant and its streamers are widely developed in all latitudes. It is then a sun spot maximum type of corona. As the sun spots decrease in frequency the corona gradually changes to the form which it assumes when they are at a minimum. It becomes less brilliant and more (Continued on page 590)
Experimental Physics

By JOHN J. FURIA, A. B., M. A., (Columbia University)

LESSON SEVENTEEN

PERATURE FALLS. Newton's law adds the quantitative statement that the rate of cooling of the water body is proportional to the difference in temperature of the two bodies, i.e., the greater the difference in temperature, the greater the rate of exchange. These laws are very important in quantitative heat experiments, since they enable us to make corrections for the loss or gain in heat during the progress of the experiment and thus not necessitating tedious and difficult methods of controlling the temperature of the apparatus.

Experiment 100.

On photographing a spectrum such as was discussed in the lesson on light, we find that the photographic plate is affected beyond the limits of the shortest visible violet ray. These are known as the ultra-violet rays (meaning beyond the violet); they have been photographed and measured, having wave lengths as small as .000005 of an inch. The longest of the rays visible in the extreme red has a wave length about ten times as large. Delicate instruments however reveal infra-red (heat) rays five hundred times longer than the longest visible red ray. Heat and light differ only in the length of measuring radiations, can be bought reasonably, and can be easily made by those having access to a vacuum pump. It consists of four delicate, very light vanes fastened to the ends of a delicate cross arm of aluminum wire, mounted so as to rotate easily about the vertical axis inside of a glass bulb which has the air mostly pumped out. The vanes are blackened on one side and highly polished on the other side. When the instrument is brought into a beam of sunshine, near a gas flame or electric bulb, the vanes rotate rapidly. The writer has found it good sport to make a radiometer (see Fig. 90B) using an Erlenmeyer flask for the glass bulb and tin foil blackened on one side for the vanes. We require aluminum wire for the cross and upright, cork stopper, glass tubing, pinch cock, and rubber tubing, and DeKotinsky cement for making the connections airtight. (It is found necessary, because of leaks, to evacuate the flask from time to time.) The action is simple. We notice that the direction of rotation is such that the black side moves away from the heat source. The black surface absorbs practically all the heat radiations it receives. Hence the black sides become slightly warmer. A freely flying molecule striking the black side according to Prevost acquires some heat, and its vibrations are strengthened. On leaving the vane the reaction on the vane, according to Newton's third law of motion, is equal to the action of the leaving particle. A freely moving particle striking a shining side (colder) vane has its strength of vibrations lessened, hence its reaction on the vane is less than the reaction of the particle on the blackened side. There being more force on the blackened side than on the shining side, the set of vanes move in the direction—from the blackened side to the shining side—away from the source of heat.

Experiment 101.

Transfer the insides of a can of your favorite peach to your own inside. Punch a hole thru the can A and insert a thermometer T. Solder a circular piece of tin B at the open end of the can, and blacken it with soot. Fill with water thru the thermometer hole, and place on a wooden

Radio Around the World

On October first, a radio message was transmitted and received over a distance of twelve thousand miles. The message had been flashed from the powerful Marconi wireless station at Carnarvon, Wales, to a receiving station located at Sydney, Australia. While wireless experts were not surprised at learning that wireless messages had been received in Sydney, Australia, from Carnarvon, Wales, a distance of 12,000 miles, they pointed out that this was nearly double the distance that messages had been previously sent. It was on Tuesday, October 1, that Premier Hughes and Sir Joseph Cook of Australia, who were then in England, sent two messages from the new Marconi station at Carnarvon, Wales, to the Amalgamated Wireless Company's plant at Sydney; thus these messages enveloped the earth, for Hertzian waves move equally in all directions, as the accompanying illustration shows. This may or may not have been a freak radio transmission, said a Marconi engineer, but in any event it marks a new era in long distance radio-telegraphy. In fact, it actually brings true the dream of Nikola Tesla and many other great scientific minds, who some years ago predicted that the day would come when wireless waves would encircle our globe. As we know that wireless waves spread out equally in all directions just like the ripples in a pond of water when a stone is dropped into it, thus these powerful radio oscillations emanating from the antenna at the Carnarvon radio station, radiated in all directions, east-west-north and south; and eventually, at a point approximately halfway around the globe, or at Sydney, Australia, where a suitable apparatus had been erected, these same etheric wave vibrations were again picked up and interpreted.

Many interesting and revolutionizing developments have been and are taking place in the realm of high-speed long-distance radio-telegraphy. Among other interesting happenings in the field of commercial and government radio-telegraphy, we find that one thing that the forms of transmitters for this work have been changed in a number of cases with very gratifying results. For instance, it has been found that the Goldschmidt (German) type of radio-frequency reflecting alternator which was formerly used at Tuckerton, N. J., was so sensitive that it practically required an operator to stand alongside of it all the time in order to constantly adjust the various electric circuits and to keep the speed of the machine constant. Besides, it had a number of delicate mechanical features which required the utmost skill in the operating personnel.

Another form of transmitter which has accomplished some really remarkable work in long-distance radio transmission in the hands of skilled engineers and operators, is the high-power oscillating Poulson Arc, such as supplied by the Federal Telegraph Company and other concerns. The United States Government has used a large number of these Arc transmitters, and is now utilizing for a number of them at the present time in both large and small sizes for various requirements. A number of the larger wireless stations, including the transatlantic station at Sayville, L. I., have used a high-power Arc for transmitting. Both the Goldschmidt Alternator and the Poulson Arc are foreign inventions, and while they have shown some very excellent results in many ways, it is gratifying to note that they have both developed undesirable characteristics in operating, which have given way to an American form of high power radio transmitter of the radio-frequency alternator type, and upon which many thousands of dollars have been spent in research by one of the largest electric companies in America. Some of the best transmitting records ever made, both with regards to the clearness of telephone signals received and also their strength, have been transmitted across the Atlantic Ocean from one of the large American trans-Atlantic radio stations by means of the Alexander radio-frequency alternator.

A few years ago the radio-frequency alternator was considered more of a laboratory device than anything else by electrical engineers, and even by the radio engineers themselves. But at the present time the high frequency alternator in question has been developed to such a perfection that it really represents a remarkable stride in engineering design and technique. At present there are being used two large units of this type, one rated at 50 k.w. and the other at 200 k.w. Once upon a time these machines, in order to produce a frequency of 50,000 cycles a second, had to revolve at the tremendous and very dangerous speed of 20,000 r.p.m. (revolutions per minute) and up to 30,000 r.p.m. or more, but at the present time they have been so perfected in design as to require a rotation speed of but 5,000 r.p.m. Therefore, one of these machines can be operated without any greater attention than is required in the operation of any commercial dynamo or motor. It is possible to instruct radio operators in the handling of a plant of this type, it is said, within a few days. These machines are under perfect control at all times, and their regulation and operation either for telephone or telegraph wireless transmission is beautifully and accurately effected by means of a novel magnetic amplifier, which keeps the load on the driving motor constant, and also the frequency of the output current constant. The windings and magnetic sections are water-cooled.

For trans-Atlantic or trans-oceanic transmission, it has generally been thought that nothing else would do than a high steel mast with which to support the antenna, or else the employment of a series of tall steel masts extending over a distance of a mile or so, such as one finds at New Brunswick, N. J., or Honolulu. Nothing entirely new in the wireless field is the fact (Continued on page 588)
Harvard Hails the Naval Radio Man

HARVARD, scion of American college and university life—renowned for its classic halls and dormitories, from where thousands of America's greatest engineers, lawyers and captains of industry have been educated for generation upon generation—has capitulated to Uncle Sam's naval radio men, whom we see busily at work mastering the intricacies of wireless telegraphy in the three accompanying views recently taken at the Harvard Radio School, where several thousands of the Nation's finest are being given intensive training in Radio.

Once these classic halls resounded to the why and wherefore of the gerund and gerundive and why Nero burnt Rome. Now all one hears is the steady all-day drone of the five-hundred cycle buzzers as the keys tap-tap and the sailor boys learn how to take down a message at the rate of forty words per minute, more or less—usually less, at least for the first few weeks.

Fig. 1 of the accompanying view shows a portable radio field set equiped with manually driven dynamo and tripod, being demonstrated before a squad of junior naval operators. It is an unwritten law that the Navy is out to beat the Army when it comes to radio matters, and judging by the great interest evinced by all of the students present at the various classes, it seems that the lackies will at least give the Doughboys a hard tussle, when it comes to solving the various phases of angular impedance and the logarithmic decrement. The portable field radio set, shown at Fig. 1, has a range of about forty to fifty miles, and is intended for use with a collapsible aerial, which is supported when in use from a telescopic steel or wooden mast, about seventy-five feet high. The receiving instruments and transmitting apparatus are all contained in a cleverly designed water-proof case resembling a large dress-suit case. It is surprising how quickly the boys are trained to set up and dismantle one of these sets, and as a matter of fact, they have often set up such as frequency and power factor meters. The hot wire radiation ammeter is mounted just over the spark gap in the center of the photograph. The receiving set in front of the student seated at the table with the head "phones on, is of the de Forest type, with calibrated dials which indicate the

Fig. 2.—In the Receiving and Transmitting Apparatus Laboratory Where the Future Naval Radio Men Are Thoroughly Instructed in the Handling of Modern Apparatus.

Fig. 3.—One of Harvard's Radio Classes in "Theory."—The Exact Relation Between Radio Theory and the Apparatus Itself is Taught by the Aid of Blackboard and Instruments.

wave length being received directly in meters. Three electrode vacuum valves are used practically all together in both the Army and Navy sets, and the receiving set here shown employs vacuum valves. A naval officer is seen in the foreground instructing the operator seated at the instrument table. In the background may be seen the large-sized oscillation transformers of the spiral copper ribbon type, while at the left the copper plated Leyden jars condensers may be observed. In the extreme rear corner of this laboratory there is mounted a complete, magnetic type, automatic starter for the motor-generator set.

If you want to see an interested class of radio students, just glance at Fig. 3, which shows a class in "Radio Theory" at the Harvard Radio School. A Naval petty officer is acting as the instructor to this class, and we are glad to say that the Navy Department has succeeded in enlisting some of the best radio men in the country for this purpose. Some of the classes are very large and contain several hundred students. Unlike the average collegiate course in radio or electrical engineering theory, these future naval operators are taught theory hand-in-hand with actual practise. This is proven by the fact that wherever there is a blackboard at this school there is also invariably a more or less complete set of apparatus such as used in practise. Note the close interest manifested.
ADJUTANT-GENERAL McCAIN, in discussing the publication of war-
casualty lists, makes this statement in
regard to the transmission of numerals by
telegraph: "More mistakes are made by
telegram companies in transmitting fig-
ures than in transmitting anything else."

Groaning business men everywhere
crowd forward to testify that
statement is only too true.

For many of the errors in telegrams
there exists efficient first-aid. The over-
speeded telegrapher, losing a word, re-
places it with a neat fresh one from his
own vocabulary, fully as long as yours,
and as stout and serviceable in every way.
And this honest practice an-
wers very well, the context usually en-
abling you to restore your correspondent's
original word, if for some reason you like
it better.

For streamlining out proper names, you
rely on the wonder-
ful insight of the elevator man, who
after years of prac-
tice is able to rec-
ognize a patronymic
even when severely disfigured—such as
"Oake" for "Oakam".

But for the poor hard-working numerals
there is no "timely succor" anywhere in the
community. Every little figure has a mean-
ing of its own; and, loyal as the digits may
be to their corps, it is impossible for one
of them to "take another's place and do the
best he can." Remember what happened to
the porter who put out at Buffalo the man
in lower six, instead of the one in lower five, who'd requested the favor?!

A wounded numeral is a "dead" numeral.
But because he's the most vulnerable does-

n't explain why he's the oftener hit.

Hush now, hush! for me purpose is to
invade the guarded enclosure, and attack
the sacred cow. Is it possible that the com-
plex numerals of code-signs themselves are
partly to blame?

What, as a matter of fact, is the objec-
tion to using simply:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

—a scheme which would have occurred to
Father Adam, if he'd received a telegraph-
set along with his animals?

I assure you I'm trying to handle this
subject with tender circumspection, a mother
accords her child, or a bomber his bomb;
for it's a "commonsense" sugges-
tion, and nothing infuriates people like one
of these. I've found.

I'll never forget my experience with a
worthy lady, a neighbor of mine, who was
troubled with the rain soaking in around
her window-frames. She had carpenters
on the problem, and plumbers, and masons,
and guess most every profession but
undertakers, and they applied shingles, and

See how pretty! All of them different
from the letter-signals, and with such a
natural progression—prefixed dots in regu-
lar order, then knocking them off till you're
out of dots again.

Some cantanker-
ous old pipefitters
consider them just near
enough alike to be con-
fused. But that isn't all; plumb in
the middle of this
dream of complex
symmetry, what
meets the eye? Hor-
ors! As I live, five
dots for the figure
"1"! Forthwith arise
the voices of the
Babe and Suckling,
inquiring in plaintive
tones, "If five dots is
good for 5, why
aren't there six
telegraph isn't six
good for 6?"

As usual, the Babe
and Suckling, like
the fewest, are
easier spanked than
answered. The simple
series of taps, or any
short sounds, represen-
t numbers so naturally
that anyone, telegrapher or
not, can read them,
read them right.

Whatever else a
numeral does, it surely
ought to "nume"; and
the simple ones
do, while the code-
man's intricacies sig-
nals don't. He
seems to have drest up his cook till she's
spilled the beans.

Some say you couldn't count nine quick
dots with accuracy. But you can count
the quickest-striking clock up to 9, and even to
12. As a closer comparison, take the fire-
alarm tappers in the engine-houses and
street-boxes. They're quicker than any
clock, and furthermore, a shorter line of
numbers, forming tens and hundreds, as
"2-6; 3-8-5"; but I never heard that the
fremen often drove half a mile to box
375, for example, miscounting it for box
351, just around the corner. The dot sys-
tem's good enough for them, and they
sometime betray a regard for holding their jobs
at that.

Others say the dots would be mistaken
for letters.

 would be "E" as well as "1".
 "1" also "A".

Oh, yes, serious confusion would result:
an operator copying "EISH dollars," for
instance, might mistake the "Eish" for an
accidental sneeze, and furthermore (as
etiquette requires) and inform Jones that
Smith "will give you dollars"; and Jones
would think his message was the words to
a song, a companion-piece to "In the morn
I bring thee violets," and perhaps get mad
—because some folks don't like music.

But talk about mistakes. How about
the abbreviated form" of code-
numerals actually in use, where

(Continued on page 585)
A Rotary Quenched Spark Gap
By FRANCIS R. PRAY

THERE are a great many Radio amateurs who find it impossible to join the Service for some reason or other, and realize that the present is an excellent time to make that "perfect" set if for no other reason than the quite obvious fact that raw material will not be cheaper than it is now. Of course you exclaim; "Cheap! Why, it costs more now than it ever did." Well, yes, that may be so, but did you ever stop to think what it will cost after the war?

No doubt your next transmitter will employ a rotary quenched gap, as that is the most efficient type up to date. Should you be undecided as to the design, allow me to submit the following, as it combines the best features of the gaps on the market, besides several original ones. It is easily made with no other tools than a small bench lathe and slide-rest and the usual experimenters' hand tools. It is so designed as to combine the utmost in ruggedness with the easiest accessibility and the minimum not too much.

Parts "A" and "B" should be of brass or copper, or possibly aluminum, the sparking surfaces "C" should be heavily silver-plated in order to insure the utmost efficiency, and you know aluminum cannot be plated. Part "A" may be cast solid and the cooling flanges cut in later with a parting tool. Much care should be taken to see that the sparking surfaces are cut at exactly 45 degrees and perfectly smooth before silver-plating. The ring "D" may be made of any tough metal, since it carries no current. It is held onto the Bakelite tube "E" by eight machine screws. Tube "E" need not have a wall thicker than \( \frac{1}{4}\) inch. Disc "F" is of Bakelite also, and should be accurately fitted to "E" so as to exclude air. Eight machine screws tapped into its periphery should be sufficient to hold it in place firmly. A whole piece of Bakelite with a cross-section like "G" should be turned in the lathe and fitted into a recess in "B." This hole should be cut first and the 45-degree sparking surface turned last, because this surface should not vary the slightest in its orbit. "G" is held in place by metal washer "H." Four machine screws be all right to take a little off the motor bearings to make some, as the gap's adjustment depends on this feature. "P" and "Q" are large washers. On the right end of part "M" a small recess is drilled just large enough to hold a single ball bearing. Axle grease or vaseline is put in the hole to make the bearing run easily. By turning knob "K", the sparking electrode "B" is moved to and from the electrode "A." When a satisfactory distance is found by experiment, the lock-nut "K1" is screwed up tight. In assembling the gap, turn "K2" as far up as possible and unscrew the machine screws slightly at "R." The holes for these machine screws in the rim around part "A" should be somewhat larger than usual so that when part "A" is fitted to part "B," "A" may be moved around until it fits cone "P" snugly. Then the screws "R" are tightened and gap is ready for use. If desired, a hole may be bored at "S" and a small tube tap in thru which gases may be forced for experimental purposes. An outlet may be made at "T." Holes should be bored to ventilate the motor at points "U" and "V" all around the tube.

A Detail View of Rotary Quenched Gap, End-Play Shaft Regulator.

AIRMEN USE FALL AS RUSE TO FIND HIDDEN WIRELESS.

Residents of Glen Cove, L. I., who a short time ago had been wondering and complaining about the continual flying over their homes of airplanes from Mitchell Field, Mineola, were amazed when it became known that Department of Justice agents have been searching the city for an alleged hidden German wireless plant, said to have been discovered thru efforts of the airmen. The wireless plant is declared to have been located in the attic of a house in the exclusive Red Springs section of Glen-Cove.

For days airplanes have been hovering over the city. Two machines came to grief, and the pilots were taken into nearby houses. Now it is said that the accidents were deliberate, with the intention of gaining admittance to the suspected house. After being picked up, presumably unconscious, and carried into a certain house, one of the airmen, while left alone, is said to have fired the concealed wireless.

HOW TO MAKE BUZZER GIVE HIGH TONE.

Being in need of a buzzer giving a high pitched tone I took an ordinary call buzzer, removed the armature and \( \frac{1}{2}\)-inch from the end of the contact spring I wound two turns of No. 22, B. & S. bare copper wire around the armature under the contact spring, and two turn around the armature and over the spring. Then I twisted the ends of the wires together tightly. When I replaced the armature and adjusted it I had a high tone buzzer, which made hardly any noise to the ear, but using a telephone receiver it almost "raised the dead.

Contribute by GEO. F. HARRINGTON

A Simple Trick For Making Any Buzzer High Tone.
DETECTOR BUILT ON ATTACHMENT PLUG.

Herewith is a drawing of a "receptacle detector." Any number of detectors can be made and different ones screwed in as needed.

The base is made from an old wall type receptacle or other kind of receptacle. The detector container is made from the bottom of an old attachment plug. The plug screws into the receptacle and the detector is then ready for use.

Contributed by E. T. J.

A CLEVER WIRELESS PRACTISE SET.

Take an old tuning coil, remove the sliders or slider and on each corner of the top of the end support tack on two thin wooden sticks, such as kite sticks, and let them project over about 4" at one end. If a tuning coil is used, bring out each end of the winding as shown in coil No. 1. Connect telephone receivers as shown in diagram.

To make coil number 2, take an old curtain pole or a piece of broom handle. Saw off a piece about one inch in length. Now to make the end, take an old piece of heavy cardboard and cut out two circular pieces about two inches in diameter. After finding the exact center of your cardboard, take the round piece one inch in length, and attach the two cardboard discs, one at each end. After completing, wind full of No. 16 or 18 insulated magnet wire and hook up as shown.

By depressing the key the battery is connected with coil No. 2; the magnetic lines of force travel from coil No. 2 to coil No. 1. By operating the key according to the coil, the sound will be heard in the receiver, the same as in long distance wireless receiving. This method is fine for learning the wireless code, as the sound produced in the receiver can be varied in strength by shifting the coil No. 2 along the slide strips on top of the coil.

ELECTRICAL EXPERIMENTER

A PERFORATED TAPE CODE TEACHER.

After reading the description of various contrivances for teaching the code, I thought I would try to make one of my own design. Here is a description of it. Referring to the illustrations, A is a tin can cover, the one represented in the figure being 7" in diameter. This will take a record 22" long, or long enough to hold the entire alphabet, minus the figures. It has a grooved pulley about 2" in diameter fastened under it on the center by 4 screws. A hole is drilled centrally thru both pulley and can cover. This had better be done before fastening them together. Procure a base of suitable size, and on each end tack a piece of tin 2" square with a column in the center. Fasten an insulated wire over one tack and run this to one binding post.

The can cover should have a small piece cut out of its edge 1/16 of an inch wide, as at B. Two springs shaped as at C are soldered to the can cover inside at D. The record is a strip of paper about 24" long, with the dots and dashes cut out with a ticket punch. The ends are past thru the cut in cover edge and fastened under the ends of the springs. The cover can now be mounted on the base, over the piece of tin. Put a couple of washers under it, and fasten it down with a screw. Put a washer under the screw head too. The brush is made of spring brass shaped like E. Cut slits in the end so it will be turned to make contact with the can cover thru the dents as shown in the tape record. A driving pulley is now mounted on the other end of the base. Put washers under this too. Screw a handle on to turn it by and have a hole in the handle large enough to turn freely on screw holding it. Connect this pulley with the small one with a strong belt. Put a piece of rubber hand in it so it will always be tight. The pulleys need not run exactly true. Connect the brush with the other binding post and the code teacher is finished. In making the record repeat the same letter three or four times in some of them, as it is necessary to hear them over and over again to remember them. It is to be remembered that the instrument is connected in series with a buzzer or sounding battery.

Contributed by A. E. HERSEE.

AN Imitation "STAGE" RADIO.

Having need of an imitation wireless sending station for use on the stage that was to operate in semi-darkness, I hooked up a buzzer and electric light globe (paint ed blue), so that when a contact was closed it would connect both of them as shown in the diagram. The buzzer represents the noise of the spark discharge and the globe, represents the light that the spark throws off. The contact is to be closed by the operator (actor) pressing the key on the stage. The buzzer and the light, of course, are not to be seen by the audience. They may be placed behind a box or some other object on the stage. The buzzer should make the loudest noise possible. When this apparatus is used in the semi-darkness it will prove very satisfactory.

Contributed by G. B. PENNBAKER.

HARD RUBBER PANELS.

Go to the storage battery station in your town and ask for some large size battery jars that have been discarded. These can be procured for little or nothing. Set these in hot water until they are pliant and then with a hack-saw cut so that the jar cuts two sides at once. If the rubber becomes stiff while sawing, immerse it in the hot water again. After it is washed it can be polished with linseed oil and shellac. It can be drilled with a metal drill. If one piece is not of sufficient thickness, two pieces may be fastened together, rough sides touching, by means of the screws of the apparatus.

Contributed by DONALD HUCKE.

ROUND TRANSFORMER CORES.

In cutting the sheet iron laminations for the "legs" of transformer cores, make them of different widths, i.e., cut them narrower as they get farther from the middle. The legs will then be round, rendering the transformer much more efficient and also easier to wind on the coils.

How to Make a Seven-Inch Reflecting Telescope

By LATIMER J. WILSON

The desire to see the planets thru a telescope of greater power than the one which came within the writer's limited means financially is responsible for his accomplishing the task of making a telescope of considerable efficiency. The grinding, polishing and figuring of a glass speculum is not beyond the average ability, and such an accomplishment is far more satisfactory than the purchase of a refracting telescope of small size. Indeed the service rendered by a home-made 11-inch reflecting telescope has compared favorably with that rendered thru several months' experience with an 11-inch refractor of the best construction.

A seven-inch speculum is less difficult to construct than a ten or an eleven-inch, tho it is powerful enough to disclose details on the discs of Mars and Jupiter, Saturn and the moon, and will present splendid views of the wonders of the milky way. But if one wishes to attempt a larger size he may do so by following the methods described here, increasing in proportion the length of stroke in working and the quantities of material.

The concave mirror, or speculum of a reflector performs the same service as the lens of the refractor, it brings the rays to a point in the focal plane thus forming a real image of an object. This image in both telescopes is magnified by the eyepiece, various eyepieces being used to furnish different magnifying powers. It is obvious that the quality of the image must be perfect to permit of magnification.

The materials for a seven-inch mirror in 1910 cost about $5, including the glass discs.

There will be needed two discs of common plate glass, seven inches in diameter, one-inch and one-half an inch in thickness respectively. The thicker disc becomes the speculum, the other the "tool." The thickness of a glass speculum should be in proportion to its diameter about as 1:8.

Two or three pounds of borundum No. 80, one or two pounds of No. 120 and two pounds of Grade E FF will be needed for the grinding. One half a pound of Jeweller's Rouge (iron oxid) and about three pounds of Burgundy pitch, two cakes of beeswax, four ounces of turpentine and a pound of resin are required for polishing. These, with a few chemicals needed for silvering the finished mirror, complete the list of ingredients which one must purchase.

The one-half inch glass disc, edges ground smooth and top edge of the rim slightly bevelled, is cemented with pitch to a wooden block ten inches in diameter. The block is then made fast to a rigid support, a post or a barrel that has been firmly fastened to the floor. The worker must be able to walk freely around the support and must have plenty of room for the necessary arm movements in grinding and polishing. The one-inch thick disc, the future speculum, is cemented with pitch to the center of a circular wooden block six inches in diameter on the top of which is screwed a handle. In manipulating the speculum over the glass tool the hand must at no time come in contact with the glass of the speculum. The heat from the hands is sufficient to produce a perceptible effect in the final curve.

The No. 80 borundum (or emery) is made damp with a little water and is spread thinly over the tool. The speculum is held by the handle in such a manner that a very slight pressure from the side of the hands is upon the wooden block; it is then moved forward and backward across the tool, the worker rotating the speculum all the time by means of the block and the handle. As the grinding proceeds the worker walks around the support in a direction contrary to the direction in which the speculum is rotated. The speculum should be moved forward and backward a space slightly greater than one-half the diameter of the disc. This motion tends rapidly to cut away the center of the upper disc, at the same time cutting away the edge of the tool, making the latter convex and the former concave.

The amount of concavity necessary for a focus of sixty inches is equal to the arc subtended by a radius of 120 inches. Roughly it can be determined by frequently examining the surface of the speculum in sunlight during the stages of rough grinding. Wet the disc and hold it so the sun's light will be brought to the position of best definition, indicated by the smallest disc of the solar image. When the distance from glass to image measures about sixty inches, the rough grinding is complete.

The successive stages of the grinding are devoted to refining the curve and eliminating the pits and scratches caused by the coarser particles of borundum. It will be well to subject the No. 120 grade to a series of two washings. Mix the whole of it into a receptacle holding two gallons of water and...
water, stir well and immediately pour off all the sediment. This will be used for the first stage of fine grinding. The portion that was poured off should be allowed to settle for ten seconds and then all but the water and sediment contained in the lower part of the vessel again poured off. These sediments labelled 1, 2 and 3 are to be used in the first, second and third stages of the fine grinding.

The stroke in grinding with the finer grinds is progressively shortened. Moving the specimen forward and drawing it backward a space of one-third or one-fourth the diameter tends to keep the curve concave, and gradually to produce a spherical form. Shorter strokes tend to flatten the curve and during the final two or three hours of fine grinding the strokes may be no longer than one and one-half inches.

The FFF Grade of the flour of carborundum is subjected to several washings as follows: (a) the coarsest 8 seconds; (b) 20 seconds; (c) 1 minute; (d) 10 minutes; and (e) 30 minutes. The particles held in suspension in the washing that is left after standing 30 minutes are so fine that the liquid seems almost to be pure water. Great care should be taken not to permit coarser particles from getting mixed with the finer grinds when they are placed upon the convex surface of the tool. Plenty of water must be used during the fine grinding to prevent the binding of the surface as it is manipulated over the glass tool.

The final surface when the fine grinding is complete will present an appearance of a thin film of dried milk spread upon a piece of transparent glass. Black type well spaced and lighted one-quarter of an inch in size should be easily distinguishable as viewed through the ground surface, if the back surface is of polished plate.

Next the Burgundy Pitch is melted and strained. It is then thickened with resin or thinned with turpentine until when cool (at the room temperature) it permits a slight impression to be made with the thumbnail when pressed into it. The grinding tool is cleaned and a strip of surgeon's tape, or lantern-slide tape (paper) is stuck to the glass circumference so that it will protrude about one-quarter of an inch all around above the surface. The melted pitch is then poured on the tool and allowed to set an instant.

The speculum is painted with the rouge, which has been mixed with water and only the thin portion of which has been removed for use, thus assuring only the finest portion, avoiding coarse particles. It is very important that the speculum be kept thoroly wet with rouge and water when it is placed upon the warm pitch and gradually permitted to rest upon it until the surface of the pitch has assumed the curve of the speculum. The pitch is then reheated by passing a gas flame across it rapidly until it is soft enough to permit squares to be pressed into it. These squares must be spaced one-quarter of an inch apart by pressing a wooden foot-rule in lines at right angles, the lines being one inch apart. A reflected light from the center of the tool but should be sufficiently eccentric to allow only one corner to be in the exact center. When the squares are formed the grooves can be cut out very clean with a sharp knife, after which every particle of the debris must be washed off the polisher which is again heated by the gas flame and coated with a mopping of melted beeswax. The speculum is again painted with the rouge and is gently pressed upon the square surface for a short while it will shape the surface into perfect contact. Then the polishing can begin, the purpose of the squares being to distribute the rouge and to assure even polishing. Frequent application of rouge is necessary.

The strokes are at first as long as in the coarse grinding. When a sufficient polish appears the mirror can be subjected to the well-known Foucault Knife-edge Test. Always before testing the mirror should be permitted to rest for fifteen minutes in order to cool all the heat from the friction of polishing has subsided, otherwise a true test of the surface cannot be made. In a darkened room the speculum is placed in an upright position and directly in front of it at a distance equal to the radius of curvature (in this case 120 inches) is placed a lamp having a bright flame hidden entirely by a metal chimney. Opposite the brightest part of the flame is a needle hole so directed toward the mirror that the light from it will be reflected back to a point within ten inches of the lamp at its side. The brighter the light and the smaller the needle hole the better will be the result. The writer has used satisfactorily a small arc projection lantern having a prism in the path of rays and the light from the lamp is directed through a needle hole in a piece of tinfoil glued to the side of the prism. This enables the worker to make the test at a distance of only a few inches. The light from the needle-hole illuminates the mirror as seen at the principal focus. Inside this focal point the image of the lamp will be seen upright; beyond the point it will be seen inverted, but at the focal point the light from the bright needle-hole will illuminate the disc so that no image will appear except the mirror's bright disc. An opaque object such as the straight edge of a knife blade mounted upright can be passed across the cone of rays before the eye. If the shadow advances as a straight line in the same direction as that of the moving knife-blade the mirror is too near the mirror; if it comes from the opposite direction it is too far, but if the mirror gradually darkens the blade is in the best focus and the test can be made.

Imagine the surface of the mirror illuminated from a direction opposite to that from which the blade is moved. If the surface then presents the aspect of a ridge around the edge and a hill in the center, the polishing strokes should be lengthened to cut away the elevations. If the mirror shows slight depression the strokes should be shortened. If a deep depression is seen and the outer portions of the disc seem turned back, the figure is that of a hyperbola and to correct it go back to the grinding, using very short strokes. A perfect sphere is indicated when the surface darkens evenly. Work first for this effect. Then to produce an approximate curve that will satisfy all demands polish for a very few moments at one time, until the surface looks like a shallow dinner plate, a very faint trace of a depression in the center. This will probably approach the parallel curve, and if not carried too far will result in a perfect speculum.

A Simple Study of Currents and Magnets

By Prof. E. H. JOHNSON, Dept. Physics, Kenyon College

ONE of the first facts that the investigator in the field of electromagnetism comes to recognize is that there is a "directedness" to the interactions between magnets and current-bearing conductors. The mystery is partly dispelled, however, when he learns that a magnet, whether permanent or due to a current in a coil of wire, can be attracted or repelled only by another magnet—that is, it is acted upon only by a magnetic field.

Now the "field" in the sense here used means the entire region throughout which the magnetic force can be detected by any means whatever. Therefore the various portions of the field can be considered to have direction, because a force has a direction. And if we try to map out a field of magnetic or any other kind of force on a sheet of paper, we will get a series of lines or arrows, not necessarily having any uniform direction. Such a map is naturally limited to two dimensions, and so will represent only some one plane arbitrarily chosen in the three-dimensional space field of force we may be studying. These direction lines in the field have been called the "lines of force," and it must be remembered that they are directions only and probably do not exist in any much more real manner, nor do they serve to enable us to form a comprehensive idea of the possible causes of the reactions we may actually observe.

To grasp the ideas involved in a clear manner, many simple experiments can be performed, but we will content ourselves with several of the simplest ones, which, tho not new, are well worth close observation by the student.

To begin with, we have the fundamental law that LIKE magnetic poles repel one another, while UNLIKE magnetic poles attract one another. Hence, according to our previous statement that the magnetic force of a magnet, as ordinarily observed in its natural North-and-South position hold directly, above it and parallel to it, a single wire in which a small direct current is flowing. It will be found that if the current is flowing from South to North above the needle, the North pole of the needle will be deflected toward the West, as shown at —a—, Fig. 1. If the current is reversed, the needle will swing to the East, as shown at —b—. Now if the wire is slpt under the compass and the preceding two steps are repeated, the deflections will be changed correspondingly, as indicated by —c— and —d—, Fig. 1.

From this simple experiment we can see that there is a definite relation between the direction of the current and that in which a magnetic pole will move if free to do so. If one imagines that he can look along the wire, of which the shaded portions in Fig. 2, represent sections, the arrow-like direction in which a North magnetic pole will move when the current is flowing out from or into the plane of the paper, Mercury.

Another simple rule covering all of the above cases, is that known as the right-hand rule, which states that if the current-bearing wire is grasped in the right hand, with the thumb pointing along the wire in the direction in which the current is flowing, the fingers will encircle the wire in the direction in which a North magnetic pole would be deflected. See Fig. 3. This rule is perhaps the easiest to remember of the many which can be given, but it should be clearly seen that they all lead to the same conclusion and that the law they seek to illustrate is perfectly definite and invariable.

So numerous are the experimental possibilities for demonstrating this principle that it is in fact difficult to escape its application in any branch of electrical science. Without it electromechanical machinery would be impossible. For the present, a few simple constructions will suffice to show how repeated or continuous motion may be obtained with the use of simple deflection as in the case of the compass needle, and also the examples here given are in the nature of toys long known to anyone familiar with the subject, they will be highly instructive and well worth the time and effort involved in their construction by anyone who is not thoroly acquainted with them.

Secure a glass tube or slender lamp chimney (A, Fig. 4) about 6 inches long and about an inch or so in diameter. Into its ends fit two corks, B and C. Thru the lower cork, C, thrust an iron rod, D, about ¾ inch in diameter and 3 inches long. Around the lower half of it wind a couple of layers of insulated wire (any size from No. 18 to No. 24) and carry one end of the wire up thru the cork, shown in Fig. 4, so that it may be surrounded by a layer of mercury, F, which, in turn, should not quite cover the upper end of the iron rod. Thru the upper cork, B, pass a short length of bare copper wire G, and then hang it from a loosely a sufficiently long piece of similar wire, H, to just encircle the mercury. This device can be mounted in an upright position on a block in any convenient manner.

(To be continued)
Spectroscopic Methods and Spectra

A SEQUEL TO "HOW TO BUILD A SPECTROSCOPE"

By D. S. BINNINGTON

PART II—Conclusion

Method No. 1.

THIS method of obtaining the spectrum of a gas, is the only one that can be used, and has several difficulties in the way of home-made apparatus. The principle of the method is, that the required gas is sealed up in a tube in an exceedingly dilute condition, and by means of platinum electrodes, the tube is connected to a spark coil. The tubes are of the shape shown in Fig. 7, and the narrow portion is placed in front of the slit for inspection. These tubes cannot be home-made without special apparatus, etc., but can be purchased from dealers in laboratory apparatus with various gases, such as oxygen, hydrogen, carbon dioxide, etc. The price of these varies somewhat, but the lowest is about $1.50 per tube. They can also be obtained filled with the rare gases, argon, helium, neon, krypton and xenon, but these will not interest the average experimenter as they are only for use with delicate apparatus, besides ranging in cost from $5.00 to $15.00.

To those who are interested in this branch of the work, however, a tube can be purchased that, coupled with the fittings of a stop-cock is then closed and the tube is ready for use. This tube possesses the advantage that it can be filled with any desired gas for one outfit. But care must be taken to exhaust it thoroughly, else complications will ensue. It should be noted, too, that all the materials used to prepare the gas must be as pure as obtainable. The gas should be washed with a proper wash liquid, and dried over concentrated sulfuric acid, Calcium chloride or any drying agent. These details, however, can best be obtained from

good laboratory, will give excellent results.

Method No. 3.

This method is really the simplest of all three, but has some disadvantages, however, which eliminate it from certain classes of investigation. It consists, essentially, in vaporizing the material in the electrical arc.

A quantity of carbons about ¾" diameter should be cut by means of a small saw into pieces 6" long. One end should then be roughly rounded off with coarse sandpaper or a file. It should then be clamped in a vise or between two boards, and a hole drilled in the center of the end about as large as a pencil lead, and about 3/16" to ¾" deep. A mixture of the material to be used and its own bulk of charcoal is then powdered, well mixed and packed into the hole. It is then placed opposite a plain carbon in a horizontal position, and an arc struck between the two. A small amount of the material is vaporized into the arc, the temperature of which is sufficient to vaporize any known material. As, if this method is used, fresh carbons must be prepared, it is convenient to make a small stand to hold them in use and so that they are easily interchangeable.

An apparatus for this purpose has been designed by the writer and is shown in Fig. 9. One carbon is fixed, while a clip is made into which the prepared carbons can be inserted. A water rheostat is used in series with the arc on 110 volts. A standard spectrometer as used in the laboratory, note how the prism is clamped to a rotatable table. The telescope and collimator are adjustable and the base has three leveling screws.

The finished electric arc for producing various spectra. A water rheostat is used in series with the arc on 110 volts.

A text-book on Chemistry. This covers the field of work on gaseous spectra for amateurs, but, however, hardly touches it from the scientist's point of view, as the subject of gaseous spectra has probably the widest field of all spectroscopic work, and merges to a considerable extent into X-rays, radioactivity and similar fields of electrical work connected with vacuum tubes, and basing their theories on electrons, etc. Indeed this subject belongs really to Physical Chemistry, which correlates all that is known from the chemical, electrical and physical standpoints, and places it on a common foundation.

(Continued on page 594)
An Electrical Photo Printer

By DR. E. BADE

The electrical photo printer is made from a wood or metal box eight inches in length, nine inches in breadth, and twelve inches in height. The cover, one inch thick, extends two inches on each side. It is made in two parts but it differs from those usually employed in that an iron flange, E, is attached to it, which hooks the presser block and holds it in place at E. The same piece of iron also presses the rod G, which, by means of levers, pulls H downward. H fits into another pair of levers within the box which lift the red cloth screen, J. The lever is held in place by the brace. The screen is made from a framework of wood and covered with suitable cloth. The screen is in its normal position when it is down. The negative and the paper are placed upon the glass plate and the mask is adjusted. As soon as the press is brought down to hold the picture in place, the rod is pushed down by the flange, the screen lifted by the system of levers, and the light from the bulb will print the sensitive paper. This forty watt bulb, which is constantly lit, is

AUTOMATIC GASOLINE ENGINE "STOP."

This device is used to stop a gasoline engine that drives an air compressor automatically, when the pressure has reached the desired point.

We found it impossible to get a safety valve that would not leak air, so I designed this device and have found it entirely satisfactory. All that is necessary to do is to start the engine and "forget it." When the pressure gets high enough the engine stops.

The circuit breaker, A, is made from an old bell. The two springs, B and B, were taken from an automobile tire valve. The switch handle, C, is made of fiber (wood or hard rubber). The armature, D, is riveted to the steel strip E (old hack saw blade). F and F are merely stops to prevent springs from pulling levers too far. G is a pivot connecting H to I. The hook J is of steel (case hardened) and catches in the steel hook (which is hardened) on the end of E. E is pivoted on the steel pivot K (piece of hack saw blade). The pivot K has a projection which goes thru in E to keep E from slipping out of place.

In regard to the pressure gage it must be placed between pump and check valve. At each impulse of the pump the hand jumps slightly. One of these jumps is enough to close the circuit for an instant. Then the hand falls back a little and prevents start. A small hole must be drilled thru the dial at the desired mark, a corresponding hole is drilled thru back of gage (shown in drawing). The bolt A has a wire soldered to its head. This wire extends thru dial of gage and has platinum point soldered on its side. Bolt A must be insulated from gage by means of fiber washers at B. The hand C has a platinum point soldered to it so it will make contact with the point on A. When the point on hand C touches point on A the circuit is closed. The magnets in the circuit-breaker pull armature D down, allowing arm C to fall back, thereby breaking the ignition circuit and stops the engine. To start the engine again the arm C is pushed in again.

Contribution by L. E. PARSONS.

TRAIN REVERSING SWITCH.

If you have an electric train with a permanent magnet field then reversing the current would reverse the motor. I have designed this reverser, which is combined with a variable resistance unit.

The switch handle is made of fiber or hard wood and the contacts on it are made of copper. The resistance coils can be old shade-roller springs.

Contributed by BURTON McKIM.
LATHE CHUCKS.

A OTHER form of independent jaw chuck is found useful in chucking irregular work. This has four screw clamps or dogs of the form indicated in Fig. 5, which are bolted by means of a nut to the chuck or face plate. By tightening the large threaded screw against the work, it will be securely fastened for operation.

A very useful form of chuck which depends upon adjustable screws for holding the work, is the bell chuck, and this is shown in Fig. 6. It consists of casting or forging made in the shape of a bell, C, which is bored and threaded at the back to fit the lathe spindle. The work, W, is held between the screws S.S.S., which are placed at regularly spaced intervals around the bell portion of the casting. In the side view of this chuck, two sets of screws are shown, one set behind the other, which enables the work of considerable length to be adjusted centrally, while the work is more securely held than by one set of screws.

At times when the work is heavy at one side, or when an angle plate is used in chucking, it is necessary to bolt a counter-balance on the face plate opposite the heavy part. The distance from the center of the lathe to the heaviest part of the work should be the same distance to the center of the counter balance; otherwise the work will run out of center or out of true, and thus will not be round when machined, owing to unbalance.

A drill chuck is usually very handy, and is made much smaller than those described above. It generally contains three jaws. A most common form of drill chuck is shown in Fig. 7. The drill is secured between the jaws by turning the knurled outer shell of the chuck. This operation automatically tightens up all the jaws.

For especially accurate or precision work, another form of chuck is used, which is called a split- or draw-in chuck. The chuck and method of securing is shown on precision head stock, Fig. 8. The draw-in chuck, I, consists of a cylindrical tube with a hole in the center of proper diameter. One end of this tube is turned conically, and its face split in three equal parts, by three slots. This tube is threaded on the opposite end and fits into a rod, R, protruding thru the spindle, and its end secured to a handle, H. Looking at the construction of the head of the spindle, it will be noticed that by drawing the split cylinder towards the rod, R, and turning the handle, H, that the conical end will be drawn in, thus making the hole of the cylinder smaller. If a rod of the proper diameter were secured in this hole, it would be tightened up and clamped in it. This cylinder with the conical end and split face is called the chuck, and the rod, R, is called the draw-in attachment of the chuck.

There are a great many sizes of split-face chucks. Each and every one has a definite size hole, and can be used only with work having its diameter approximately equal to the diameter of its chucking hole. This, of course, gives a standard hole, and for this reason is used for precise model and other work, where accuracy and speed in centering is necessary.

In order that the amateur may not be confused with the terms, it may be stated that the word "precision," as applied to the lathe, has several meanings. One of these concerns a lathe, no matter on what principle it is built, which if carefully constructed, is capable of producing precise work within the limits of one type. The real meaning of the word, however, is technically applied to a particular type of tool, which, in addition to the first-class workmanship, is also constructed on a definite plan, so that precise results are attained mainly from the method in which the machine is set up. A true precision lathe is generally a tool for lighter work. The mandrel is so designed that the bulk of the precision accessories are attached to it by means of a draw-in spindle or rod, and not at all by means of a threaded nose.

It is well to remember, and it is a proven fact, that the screw-on principle of attaching chucks to a lathe is far from desirable from the point of accuracy. However carefully the nose may be screw-cut and the chuck fitted, sooner or later, due to dirt accumulations in the chucks and wear on the thread by continually screwing in and unscrewing it, and on the faces of the chuck adapter, the attachments work out of alignment. In addition, the method by which so-called self-centering is accomplished and which was described at the beginning of limited wearing area of their jaws, only serves to make matters worse. For most purposes, in small power engineering, at any rate, the usual method of screwing on chucks is quite accurate enough, in view of the fact that it is the usual thing in heavier machine-tool practice. In some classes of work, notably in watch, clock and instrument making, this matter becomes particularly important, and it is here that the want of a true precision lathe results in its production on the line just mentioned. Also in heavier machine work where large quantities of interchangeable parts have to be made on repetition lathes of the turret-head kind, the split-chuck principle is used. Practically all model shops, especially those turning out instrument parts are equipped with precision lathes of this type. (Continued on page 594)
SULFUR: History.

Sulfur was known to the ancients, the alchemists attaching a great deal of importance to it. They thought it was one of two or three primary substances. The Greeks and Romans utilized it as a medicine.

Preparation.

The crude sulfur earth and masses of ore are piled with a small amount of fuel in heaps over depressions in the ground. These heaps are then ignited, the Sulfur melts, runs down, and is collected from the hollow beneath. The liquid solidifies and this product is exported.

So that the reader will not be confused by the names Brimstone or Roll Sulfur, and Flowers of Sulfur, it will not be out of place to distinguish between them at this time. Sulfur, on the contrary, is the crude unmoulded sulfur, which is used for technical purposes only. Flowers of Sulfur, is the so-called sublimed sulfur, which consists of a mixture of the rhombic and amorphous varieties (to be described later).

Sulfur is refined and made into Flowers of Sulfur by the process of sublimation. The crude Sulfur is contained and melted in a vat, which leads to retorts, thru which the sulfur is diverted (see Fig. 152). All the air is excluded during this passage, and after reaching the retorts, then vaporized by heat situated directly under the retorts. In this state it is then past into a chamber, on the cold walls of which it sublimes. As the walls of these chambers become heated, the sublimate melts and the liquid is drawn off by means of an outlet situated at the bottom of the chamber, into cylindrical moulds. It is in this form that it is called Brimstone.

Sulfur can be obtained from the Calcium Sulfid which is obtained as a waste product in the LeBlanc soda process. This waste product, before removing from the leaching vats, is subjected to a current of air, by which the sulfid is partly converted into sulphur and thiosulfate. The calcium thiosulfate may be used for the preparation of Sodium Thiosulfate ("Hypo") which is used in considerable quantities in photography, or the mixture may then be treated with Hydrochloric acid,

2CaS + CaSO₃ + 6HCl = 3CaCl₂ + 4S + 3H₂O

The recovery of sulfur from the purifiers in the gas works is practised to a large extent in England. The gas, of which Hydrogen Sulfid is a constituent, is past over moist ferric oxide, thus,

2Fe₂S + 3H₂O + 3O = Fe₂O₃H₃O + S

The recovered iron oxide, mixed with Sulfur, is then exposed to another quantity of the gas, and repeatedly regenerated until the mass contains about 50 per cent of Sulfur, the latter being recovered by heating the mixture.

Allotropic Forms.

Octahedral or Rhombic Sulfur. This is the form in which it occurs in nature as well as that form in which it crystallizes from Carbon Disulfid.

Prismatic or Monoclinic Sulfur. This form is obtained from the cooling of fused Sulfur. On heating Sulfur in a Hessian crucible until melted, allowing to cool until a crust forms on the surface, then quickly pouring out the liquid portion, the crucible will be lined with long, brilliant transparent crystals, having the form of monochine prisms, these becoming opaque after twenty-four hours at ordinary temperature. If these crystals are examined under a microscope, they will be found to be made up of minute rhombic crystals. This form has a specific gravity of 1.96 and melts at 120 degrees, and is soluble in Carbon Disulfid.

Plastic or Amorphous Sulfur. This may be prepared by carefully heating Sulfur to 330 degrees, and then pouring, in a thin steam, into water. The product in this case being an amber-colored, plastic mass, which may be drawn out into threads or kneaded between the fingers. This is called the Plastic variety. The specific gravity of this form in 1.95, which is insoluble in Carbon Disulfid. Due to the fact that it quickly reverts to the rhombic variety with the evolution of heat, no melting point can be assigned to it.

(Continued on page 577)
SECOND PRIZE, $2.00

NIFTY SLOT-CUTTING WRINKLE.
To cut slots (which is quite difficult to do neatly with a thin file), hook into your hack-saw frame, instead of the usual single blade, two, three or four blades, according to the width of the slot desired. Be sure to have the teeth of all blades point the same way. A beautiful even slot is the result.

Contributed by THOMAS REED.

MAKING A SWITCH FROM AN OLD FUSE BLOCK.
To make a switch from an old fuse block is an easy matter. All the material that is necessary is the fuse block, a piece of brass rod the right length, and a wooden handle. I used the handle of an old shocking machine. A hole is bored in the handle so as to hold the brass rod snugly. The clips that originally held the fuse are now used to hold the brass rod. Connections are made by running the brass rod in the clips in place of the fuse. When the switch is not in use the rod may be taken off and taken with you, so no one can tamper with the switch while you are away.

Contributed by RUSSEL MAC COMISKEY.

FIRST PRIZE, $3.00

A HOME-MADE "LOCK-SWITCH." Having need for a lock-switch, I made one as shown in diagram. On a base, B, I mounted a padlock, C, with screws. A wire was soldered at C and connected to binding post D. A block of wood was mounted at A and a strip of brass, F, was fastened to it. The brass spring was connected to post E. The strip of brass was bent until a good contact was made when the padlock was open.

To make this switch more effective, a cover should be put over it, with an opening where the key otherwise fits. A little extra work is expended on this, but the result is more than sufficient to build a neat lock-switch at a low expense.

Contributed by E. D. PAPKEE.

A SIMPLE PADLOCK SWITCH FOR CLOSING ALARM BELL CIRCUIT WHENEVER LOCK HASP IS OPENED. A simple padlock switch for closing alarm bell circuit whenever lock hasp is opened. Inserting the key and a pin, H, should project thru the cover so that the lock can be shut.

Contributed by E. D. PAPKEE.

A CENTRALIZED BUZZER TELEGRAPH AND TELEPHONE LINE.
This scheme comprises one buzzer, 2 dry batteries, 2-75 ohm 'phones 1 m.f., connected at either end but at the center of the system preferably. Only one of each is necessary to work both ways. Where two Amateurs reside in the same house or on the same side of the street this will go a great way towards keeping them in trim until after the war. Now, brother experimenters don't wear long faces because you can't use your radio outfit. Hook this up and forget your grouches.

Contributed by JOSEPH C. HANHAUSER.

TRY THIS STUNT ON YOUR PIANO.
A very unique and entertaining (also sometimes exasperating) attachment may be easily installed by musically inclined experimenters, for their own amusement.

Procure a telegraph sounder and a few dry cells. Consult the accompanying diagram, and the soft pedal will do the rest.

Contributed by J. J. COPeland.

HOW TO REMEMBER OHM'S LAW.
I present herewith a simplified method for figuring Ohm's law which I have never seen in print. It might appropriately be termed 'Ohm's Law in a Nutshell.' In the formula E represents voltage, A amperes, and R the resistance in ohms. To find any term, cover it with the finger. Thus to find the amperes we have the fraction E over R, or volts divided by ohms; to find voltage we have A times "Ohm's Law in a Nutshell."
Never before has there been such a big demand for trained graduate electricians, and never at such splendid pay. There are not enough trained men in the country. More men must be trained to meet this urgent need. Here is your opportunity!

You — yes you — are wanted, but as a TRAINED ELECTRICAL MAN. In these days there is no place for idlers, and there is no place for the untrained man. In civil or military life he is not only useless, but he is a burden. It is now up to every one of us to prepare to be just as useful to the country as possible. And after the war the untrained man will be up against it still worse, because he will be unable to compete with the skilled men now being trained. How does this hit you?

BE A CERTIFICATED ELECTRICIAN
Earn $45 to $100 a Week

There is only one thing to it; you simply have to prepare for a real business if you expect to ever get ahead; and I can easily train you so you will soon be ready for a fine Electrical position, if you will only follow my advice and instruction. My system of Instruction at Home, without interfering with your work, is simple and clear yet thorough and complete. A few months snappy training of the right kind will prepare you to earn a good salary and start you on the way to a big success.

I have trained thousands of men and I know what I can do for you. In fact, I know so well that I will Guarantee under Bond to return every cent of your tuition if you are not entirely satisfied when you receive your Electric Certificate as a graduate of my school.

How have other successful men gotten ahead? Not by idly drifting along, but by preparing for bigger things. They have no more brains than you, but they have trained them. You can do the same and soon be earning a fine income.

L. L. COOKE, CHICAGO ENGINEER
DEPT. 20Y
441 Cass St.
YOU'RE WANTED!

CATED ELECTRICIAN

You Men of Draft Age  Don't delay taking up this course because you may be drafted. That's the very reason you should begin immediately. It is your patriotic duty to make yourself worth the most possible to your country—and to yourself—and of course the trained man with technical education is the one who rises in rank and pay. If you begin at once you may finish the course before you are called, but if not the part you have covered will be a benefit to you. Write me about it today.

What Can You Do as a Trained Man? This is absolutely the day of the specialist. Success in any line depends upon training. What line will you take up? There is no field that offers such a wide range of application, such wonderful opportunities for financial advancement and such urgent need for more trained men as Electricity. I can very quickly train you so that you can handle your share of the business of the nation. But it is up to YOU. You must act for yourself. But if you will give me your confidence and your co-operation I will take you along the way to a real success. Fill out the coupon and send! Now.

The Only School In addition to the fact that I am Chief Engineer of Chicago Engineering Works and can help you better than anybody else, here we have large finely equipped shops where you can come at any time for special instruction without charge. No correspondence school has such equipment or can make you such an offer. You can't learn electricity from a set of books.

Special Offer Right now I am giving a big valuable surprise that I cannot explain here, to every student who answers this ad. Be sure to get this. Write today.

FREE LESSONS AND OUTFIT

Send me the Free Outfit coupon at once. Do it now! For a limited time I am making a slashing cut in the cost of tuition and giving each new student a fine Outfit of Electrical Tools, Materials and Instruments—Absolutely Free. I will also send you—free and fully prepaid—Proof Lessons to show you how easily you can be trained at home to enter this great profession, by means of my new, revised and original system of mail instruction which has proved so successful for my students.

Valuable Book Free
To everyone who answers this ad I will also send without charge my free book, "How to Become An Electrical Expert". Write for it today.

Tear Off and Mail The Coupon Now!
It will not cost you a nickel to find out all about this, and it may mean everything to your future life. Don't neglect it. Tear off the coupon right now. Fill in your name and address and send it to me. Then what I will send back to you will show you the wonderful opportunity I am offering you and how easily you can take advantage of it. Now tear off the coupon.

FREE "OUTFIT" COUPON

CHIEF ENGINEER COOKE,
Chicago Engineering Works,
Dept. 20Y-441 Cass Street,
Chicago, Ill.

Please send me at once—fully prepaid and entirely free—complete particulars of your great offer for this month.

A SIMPL E KIPP GENERAT OR.
The Kipp generator shown in the accompanying drawing can be easily and cheaply constructed. The drawing explains itself, so far as construction is concerned. The test tube should be as large as possible, but picking over a block of wood until the wood is perfectly smooth, stain and finish up in any desired style. Use no color for oak. Rosewood Stain—Alcohol 1 gallon, camwood 2 ounces. Set in a warm place 24 hours. Add extract of logwood 3 ounces, aqua fortis 1 ounce. When dissolved it is ready for use.

India Ink—Grind fine lampblack and gelatine, scent with camphor or musk essence and mold in sticks. It can be improved by washing the lampblack with a solution of caustic soda and then straining off the solution or drying it out. Transparent for Tools—Best alcohol, 1 gal.; gum sandarac, 2 pounds; gum mastic, 1/2 pound. Place all in a tin can which admits of being corked; cork it tight, and shake it frequently, occasionally placing the can in hot water. When dissolved it is ready for use. This makes a very nice varnish for new tools which are exposed to dampness, etc.

Contributed by ERNEST E. MILLER.

A NOVEL CHEMICAL INDICATOR.
In chemistry an indicator is something which tells whether a substance is acid or basic. The following is a rather peculiar one:

Place some sulfate of quinin in a beaker and add some water. The sulfate of quinin will not dissolve. Now add dilute sulfuric acid drop by drop until the sulfate of quinin is all dissolved.

To test for a basic reaction add some of the above solution to the solution to be tested. If the solution is basic the sulfate of quinin will reappear as a flaky precipitate. To test for an acid make some of the test solution slightly basic and add solution to be tested. If the solution clears the substance is acid.

Contributed by J. C. MORRIS, Jr.

EXPERIMENT WITH CALCIUM CARBONAT.
Place some powdered calcium carbonate in a vessel containing some water. The carbonat is insoluble. Now blow the breath thru the water and the carbonat will dissolve due to the fact that the insoluble carbonat of calcium is transformed by the carbonic acid gas of the breath into the soluble bi-carbonat of calcium.

Powdered or precipitated chalk is a convenient form of calcium carbonate to use.

The reactions which take place are as follows:
First: The carbon dioxide of the breath unites with the water to form carbonic acid, according to the equation:
\[ \text{H}_2\text{O} + \text{CO}_2 \rightarrow \text{H}_2\text{CO}_3 \]

Second: The carbonic acid unites with the calcium carbonat, according to the equation:
\[ \text{CaCO}_3 + \text{H}_2\text{CO}_3 \rightarrow \text{Ca(HCO}_3\text{)}_2 \]

If the solution of the bi-carbonat is heated the carbonat of calcium will again appear as a precipitat because the bi-carbonat of calcium is broken up by the heat, according to the equation:
\[ \text{Ca(HCO}_3\text{)}_2 \rightarrow \text{CaCO}_3 + \text{H}_2\text{CO}_3 \]

This latter fact is made use of commercially in the purification of water.

Contributed by J. C. MORRIS, JR.
Electric Light for Pencils.
(No. 1,274,320, issued to Cristian Edmundson.)

This electric light attachment for pencils or pens is intended for use in conjunction with a small flash-light battery carried in the pocket.

The attachment as here designed is detachable from the point of the pencil, and is also provided with a switch for closing the lamp circuit. The switch is controlled by the movement of the fore-finger while writing and thus the position while writing is a natural one. The attachment may be adjusted at any position along the pencil to compensate for reshARPaning, etc. Two or more pen lamps can be used in the reflecTor.

Electric Cooking Vessel
(No. 1,274,021, issued to Howard C. Causten.)

This invention relates to a domestic kettle or cooking vessel adapted for use with an electric heating unit, the improvement being directed to the provision of a receptacle within which the heating unit properly may be removable placed so as to be below the bottom of the general volume of the vessel so as to insure entire immersion of the heating unit, with an amount of liquid which is relatively in proportion to the volume of the vessel. By the arrangement as shown, the liquid is delivered to the heating unit from a position in which soft India rubber is used. The inventor claims that the device is efficacious for the purpose of making cooking machine records, and reproducing them by means of this invention.

"Cold" Light
(No. 1,274,110, issued to William L. Barnard.)

On the order of the cold light of Dusaud, the Frenchman, this inventor provides an incandescent electric lamp having a multiplicity of filaments which are connected to a rotary switch in such a manner that when the switch is rotated by a motor, a continuous and uniform luminosity will be produced by the lamp. Each filament produces but an intermittent luminosity. In this way each filament is switched off before it produces any great heat, and thus the total heat radiation from such a lamp is greatly reduced.

Art of Illustrating Phenomena
(No. 1,270,369, issued to Charles F. Bishop.)

Ordinarily the flow of electrical current along a conductor is an invisible phenomena of course, but the inventor represents action in electrical circuits by using parallel lines to form each conductor, and then partly fills in the space between these lines with short black sections to represent the presence of a current. He also uses parallel lines of varying density to indicate different degrees of magnetization. When a large number of successive diagrams are constructed in this manner, it is evident that a very realistic effect will be produced upon the spectator, as he can visibly see the current flow around the circuit, the core becoming magnetized and the secondary discharge across the spark plug, etc.

Radio Signaling Scheme
(No. 1,271,431, issued to Roy Alexander.)

An improved method of radio signaling employing a receiving antenna designed to exclude interfering electric-magnetic waves having a frequency considerably higher than the frequency of the incoming waves. The usual arrangement of elevated antenna may be employed, but included therein at regular intervals, there is inserted a series of flat inducances, which may be of equal value, and of the form of closely wound coils. This antenna is connected in the usual manner to a tunable receiving set. Apparently a species of electrical inertia is thus imparted to the antenna system which resists the wide oscillations produced by shock.

Talking Motion Pictures
(No. 1,275,227, issued to Clyde J. Coleman.)

In this patent an arrangement is provided for establishing synchronism between a motion picture projector and a phonograph, such that this synchronism is attained by providing an escapement for one mechanism, controlled by the driving element of another, each mechanism having a separate source of power. The phonograph is placed behind the screen, and the sound passes thru openings in the same. A commutating disk controls the electrical impulses sent thru an electromagnet attached to the escapement mechanism or when attached to the picture projecting machine, so as to translate the "speed" and "register" of the film.

Direct Reading Ohm-Meter
(No. 1,275,980, issued to Harry Gould Stuart.)

The inventor provides a direct reading ohm-meter comprising two distinct elements, viz: an ammeter and a voltmeter. It operates on the principle of Ohm's law, familiar to all electricians. The movable element of the ammeter carries a calibrated scale or dial; the movable element of the voltmeter carries an indicator which extends in a direction approximately at right angles to the scale attached to the ammeter. Thus the scale and indicator overlap, and by noting the position of the indicator with respect to the scale, the total resistance of the conductor can be immediately deduced.

Telephone Transmitter or Receiver
(No. 1,270,920, issued to Konrad Bose.)

A telephonic device suitable for use in converting sound waves into electrical impulses, or electrical impulses into sound waves. The inventor provides a clever and simple arrangement of telephone transmitter or receiver of the diaphragm type, and which has operatively connected thereto the diaphragm oscillator, an auxiliary coil, and an oxidizing agent material, such as iron. This so influences the magnetic field when the diaphragm is actuated that current impulses will flow thru the circuit in which the oscillator is connected. Further, the passage of electrical impulses thru the magnetic oscillator influences a magnetic field that the diaphragm will be oscillated in such a manner as to emit the original sounds which set up the electrical impulses thru the magnetic oscillator in the telephonic circuit. The diaphragm used is of mica. The conical helix may be made of iron or steel.

A Liquid Rheostat
(No. 1,270,808, issued to Arthur J. Hall.)

In this improved form of liquid rheostat, means are provided for automatically changing the load due to the evaporation of the electrolyte within the rheostat and maintaining a substantially constant amount of electrolyte, which may be continuously circulated thru the liquid rheostat for the purpose of dissipating the heat developed therein. Another provision is an automatic means for maintaining the density of the electrolyte at a constant value. To accomplish this an auxiliary tank of fresh water is connected with the main electrolyte reservoir, so as to automatically replenish the electrolyte whenever the volume has decreased to the predetermined amount. A pump is provided for circulating the electrolyte continuously as shown.

COPIES OF ANY OF THE ABOVE PATENTS SUPPLIED AT 10C EACH
With the Amateurs

"Amateur Electrical Laboratory" Contest

THIS MONTH'S $3.00 PRIZE WINNER—HOWARD BUCKWALTER

HEREWITH I present three photos of my Electro-chemical "Lab." All together my Electrical "Lab" consists of about 45 pieces of apparatus, such as static machine, Leyden jars, induction coils, switches, spark coil, a lamp bank, a magneto, a small dynamo, several motors, all the parts of a radio outfit, several parts of a telephone, a variable arc, and a couple of flat condensers, A. C. bells, a resistance, German Silver, and copper wire, etc. The static machine is of the Toepler-Holitz type, from which I can coax a six-inch spark. With the above mentioned apparatus I have performed a considerable number of experiments, especially with the static machine. The Electro-chemical "Lab" consists of over one hundred and fifty reagents and about sixty pieces of apparatus, among which are ring stands and clamps, test tubes, Erlenmeyer and Florence flasks ranging from 25cc. to 200cc., graduate, delivery tubes, U-tubes, Hydrometer, lactometers, 2 balances, wash bottles, a nest of beakers, a retort, a mortar and pestle, etc. The apparatus set up in the right foreground is for the electrolytic production of lead carbonat. With the apparatus I have performed a number of experiments in inorganic chemistry. The other photo shows my library, which consists of 52 purely scientific books. Also a 200 diameter microscope, a skull, and several supplement photos from the "E. E." I have all of the "E. E." issues since November, 1913. HOWARD BUCKWALTER, Lancaster, Pa.

HONORABLE MENTION (1 year's subscription to the "ELECTRICAL EXPERIMENTER")—E. BERGQUIST

ONE of the photos (lower group) shows my wireless controlled boat that I made: it goes out and shoots four small cannons off, and has two speeds ahead and two speeds reverse. It is directed by a small spark coil on board. My shop is located away from the house, so I can make all the noise I want to without disturbing the folks. Two small storage batteries can be seen under the shelf and a transformer is below the switchboard, from which I can get any potential from 1 volt up to 220, and up to 50 amperes. At the right of the large ammeter is a magnetic rectifier of my own design, which is connected to an oil-immersed step-down transformer beneath the table and from which I can draw 20 amperes D. C. current for charging batteries, and I take in quite a few for charging. In front on the shelf is an electric soldering iron, which I find very handy. On the end of the shelf is a 60,000 volt, 54 K. W. transformer. When I connect this to my Tesla coil, I can get sparks about eight inches long. On the switchboard are various instruments for measuring resistance, volts and amperes. I can obtain from 2 to 12 volts A. C. or D. C., by simply turning the few switches on the switchboard. At the extreme right can be seen my telephone, which goes to 6 other electric "Bugs." one of whom resides a mile away. I also have "Experimenter" dating back to 1913 and a complete set of electrical books.

E. BERGQUIST, Spokane, Wash.
Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! We PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $37.00!! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner: AUTO WHEEL AIR COMPRESSOR. The source of the free fuel is all in the wheels, a sectional view of which is here shown. The rim of wheel is divided into sectors and each sector is connected with a piston moving up and down in each of the hollow spokes. As each sector comes against the ground, the weight of the car forces the piston inward, compressing the air in the spokes. Near the end of the piston stroke the spoke registers with an aperture in the hollow axle, thus forming a rotary valve. The hollow axle is flexibly connected to a suitable storage tank equipped with pressure gages, etc., mounted at any convenient point on the chassis. From this storage tank the compressed air is led to an "Air Motor" connected to the propeller shaft through gears engageable by means of a foot pedal. With this system you only need to run your gas motor until the air pressure in tank is high enough to start the air motor, and thereafter you travel on air with enough surplus to run such attachments as a signal siren, air brakes, self-commencer and all the other confounded contraptions so dear to the hearts of all "motor-bugs." Inventor, J. A. Weaver, Baltimore, Md.

GETUPQUICKBED. The failure of the ordinary garden-variety alarm clock to arouse the heavy sleeper is well known, even when the expedient of placing the clock on the family dish-pan is resorted to. Again, some of us are so absent-minded that we shut the clock off in our sleep, or else go off into Slumberland again after the clock has sounded its 6 A. M. warning. Be it known to the patriotic alarm-clock public that I, D. M. Halig, have this day invented an alarm clock "getupquickbed," and it sure lives up to its word. To use it, proceed thusly: The mattress is attached to the bedstead by means of two powerful springs at the foot of the bed, which when free hold the mattress in a vertical position. At night the mattress is depressed, and the pin A is engaged by the catch B, which retains it in a horizontal or sleeping position. The alarm hammer of the clock then, instead of beating viciously a murderous gong, as heretofore, releases the catch at 6, 7 or 8 A. M., and you will rise punctually, never fear! Inventor, D. M. Halig, New York, N. Y.
The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets.
4. Questions addressed to this department cannot be answered by mail free of charge. If a quick answer is desired by mail, a nominal charge of 25 cents is made for each question. If the questions entail considerable research, work or intricate calculations a special rate will be charged. Correspondents will be informed as to the fee before such questions are answered.

### TRANSFORMER CONNECTION AND POWER FACTOR.

(964) W. B. Cain, Montreal, Quebec, Can., asks us:

#### Hook-Up for Multiple Winding Transformer.

The Primary Divisions Are All Connected on Parallel, as Well as the Secondary Units.

#### Q. 1. Why will the transformer connection I show not work?

A. 1. You have shown the transformer windings connected in series which is wrong. The transformer windings both primary and secondary should all be connected in parallel, as shown in the accompanying diagram. The transformer ought to operate with about the same efficiency as a 2 K. W. transformer.

The effect of connecting these in parallel will be that of using energy to the amount of 2 K. W. or using the normal lighting current (110 volts, 60 cycles), a current of about 18.2 amperes will be used, at 100% power factor. Such a transformer would only have a power factor of about 80%. Hence the apparent watts (volts X amperes) = 2400 watts; current then equals 22.7 amperes as indicated on an ammeter. Thus you will see that a special circuit will be necessary because the ordinary house circuit is only heavy enough to carry 6 amperes. By placing proper choke coils in the primary side, the effect of dimming the lights can be minimized.

#### DECREASE OF INDUCTANCE WITH INCREASE OF FREQUENCY.

(965) W. O. Powers, New York, writes "The Oracle":

Q. I. Re: the article on "Investigation of Inductance" in the July issue of the ELECTRICAL EXPERIMENTER, page 179:

You will note that as stated, the inductance of a coil is decreased with increasing frequency of current. According to my understanding of what takes place in the windings of such a coil this statement is not quite clear to me.

A. 1. The reason for the inductance increasing when high frequency is used, is that the high frequency current merely traverses the outside layer of the wire and produces only an outside magnetic effect; while if low frequency were used the current would traverse the whole cross-section of the wire, and all of the wire would produce magnetic effects. As the inductance is caused as a direct result of this magnetism, it consequently follows that a greater inductance value is therefore obtained with low frequency current. You are no doubt aware of the fact that a current is induced every time the magnetic lines of force vary in density, and thus you will see clearly the solution of the problem.

### TELEGRAPHING OVER TELEPHONE LINES.

(966) Everett Ziemer, Walhain, Minn., writes "The Oracle":

Q. 1. How can I telegraph over a telephone line without interfering with the talking currents?

A. 1. Regarding the connections of a telephone line to be used for the operation of telegraph instruments, see diagram. It is not a very good practise to use telephone lines for this purpose, but it is possible to use any Public Service Utilities for personal use. If the telephone line is a privately-owned affair it does not matter.

With reference to the ground connection, this can be made by using a metal plate about one foot square, and burying it about eighteen inches in a moist spot of ground. Should the ground prove to be dry, it would be advantageous to place some charcoal about the plate, and at periodic intervals pour water over it.

Another way is to connect a perforation of telephone key to the metal stand of the telephone. By manipulating the key of such an instrument the clicks of the code can be transmitted over any length of telephone line, without any batteries or other paraphernalia beyond that making up the telephone instruments. We will supply address of company supplying such a key on receipt of stamped envelope.

Free Test Lesson in Draftsmanship

Send this free lesson which explains the Chicago "Tech" method of teaching Draftsmanship by mail. Positions at big salaries are now wanted for competent men. The call of men to the war has left vacancies everywhere. Even draftsmen of limited training and experience are snapped up and paid good salaries. If you are dissatisfied with your opportunities, learn Draftsmanship. Chicago "Tech" will train you in the most practical way in the shortest time. Mail the coupon today and let us tell you about the Chicago "Tech" method. This free lesson will show you how well equipped you are to follow Draftsmanship. Enroll in the course only if you decide that you can take it up to advantage. No cost, no obligation on you to make this investigation.

Come to the College or Learn At Home

Hold your present position while training. Our experts will instruct you by mail. Only your spare time is required. You are directly under practical draftsmen and engineers. You are taught exactly the work required in the drafting rooms of big concerns. No time to put in on unnecessary studies. This means thorough instruction and early graduation.

$25.00 to $100.00 a Week

Draftsmen earn good salaries in normal times. They command extra high salaries now—and the tremendous work to be done after the war will bring a permanent and intensive demand for good men. Make your spare time count now for a higher salary and a better position.

Easy Payments

The fees for Chicago "Tech" Courses are very moderate—and you can pay on easy terms. And also—you obtain in a few months what it would take several years to acquire by ordinary methods. You can get an early start. You are soon ready to take a paying position and to quickly get back the cost of your course.

Send the Coupon

The sooner you are prepared the sooner you will be holding a job that pays a large salary and opens the way to advancement. Many executives, general managers and superintendents begin as draftsmen.

Other Institutions ask you to pay first—and then to find out later how well qualified you are for this profession. We send the free lesson first and place you under no obligations at all. Discover your qualifications before you spend any money.

The coupon will bring the Test Lesson. Free. Also information about the profession of Draftsmanship and detailed facts about Chicago "Tech" methods, the fees, terms, etc. Mark with X the branch you are interested in—or if in doubt about which course to take, write a letter stating facts about yourself and asking our advice which will be freely given. Mail either the coupon or the letter today.

FREE Instruments

Every student of the Chicago "Tech" Course in Draftsmanship receives this set of instruments, or a cash credit in case he already has a set. These instruments are of the same make and sizes as used by high salaried experts in drafting rooms of factories, shops, railroads, etc. You use them while learning—then take them right into your practical work.

Chicago Technical College,
1245 Chicago "Tech" Building, Chicago

Without obligation to me, please send me your FREE Test Lesson and other interesting literature covering the subject indicated below.
Mark X opposite work in which you are specially interested.

ELECTRICAL

THE ORACLE.
(Continued from page 566)

HOW TO PRODUCE "INFRA-RED" RAYS.

Q. 1. Asking several questions regarding fluorescent mineral effects, infra-red rays, their production, etc.,

B. Burgess,

A. 1. Replying to your first query, the fluorescent pad you speak of is probably nothing more than some granulated carbonate or zinc sulfide or willogen, all of which can be procured from one of the companies advertising in these columns.

Relative to infra-red rays: these rays are developed by means of powerful searchlight lamps, which consume as high as 20 K. W. or more. They are focused by means of parabolic reflectors, and are of such a reflector of which is usually highly polished zinc or silver. The electrodes are of carbon and some barium chloride is usually added to increase the production of the infra-red rays. The visible rays can be screened off by the interposition of a suitable diaphragm screen which consists of black fluorite, a metallic solution of iodin in carbon disulfid. The rays may be detected by the aid of a thermopile or a bolometer, the expansion of liquids, etc. We do not know anything about them. We are not aware of anyone who has done any useful work in developing them for use on powerful war machines. For most interesting information on the use of powerful, invisible infra-red rays, for radio control we refer you to the book "Radiodynamics," supplied thru our Book Department at $2.15, postpaid.

MAKING STEAM DIRECT FROM ELECTRICITY.

Karl A. Loeven, Bismarck, N. D., writes:

Q. 1. Can I produce steam from electrolytic action in water directly at a reasonable efficiency?

A. 1. Your particular idea of using electricity for the production of steam is indeed very good, because experiments of 1898 have been reached by some investigators along these lines. By referring to the March, 1918, issue, pages 360 and 361, and U. S. Patent No. 1,251,116, we believe you will obtain the desired information.

PHOTO-ELECTRICITY.

Albert S. Osgood, Ames, la., writes: "The following:

Q. 1. Refers to several queries concerning photo-electricity.

A. 1. Photo-electricity is the development of electricity by certain cells when exposed to light. They bear no relation to wireless in the common sense. There are no examples at present of P. E. C. being used in wireless apparatus. Extensive articles pertaining to electricity developed direct from sunlight, which deal with P. E. C. are given in the September, 1916, issue of the Electrical Experimenter, page 316, and March, 1918, issue, page 798.

SIGHT OF WOUNDED TO BE RESTORED BY ELECTRICITY.

An invention is being perfected in France, which, it is claimed, will restore sight to men blinded by the most serious wounds and accidents. The experiments are being conducted at the University of Paris by a professor named Kann. Work upon the apparatus is being watched with the keenest interest by Allied officials.

The perfection of the apparatus would be unusually timely, following up the reports from German sources that the Huns are planning to use new kinds of gases which blind their victims.

This useful and out-of-the ordinary, hand-book is moderately priced and highly suited to the requirements of practical men. As we have already stated, the book electrical men have been expecting for some time, is not a "penny-a-liner" or a "hassle" about theoretical circuits and design figures. It tells you where to find dozens of excellent treated on these subjects. What Mr. Burgess has done is to give the practical electrical man, artisan and engineer alike a real, hold-downed and model-size volume, which he can always have with him and find therein just what he wants.

The treatise opens with some blue line drawings of practical hook-up for motor starting boxes and control, including a description of the device, as well as drum controllers, printing press controllers, "monitor " automatic starting, reversing controllers, float switches, elevator controllers, etc. Furthermore, and which might not be speed devices, mine locomotives, street car wiring diagrams, induction motor connections and automatic tuning.

Then comes a section of wiring diagrams for all sorts of lighting circuits and 4-way control, three wire systems, and numerous articles which can be used in the shop when he comes to install such circuits.

The author gives explanations of perplexing problems met with in everyday electrical installation and insulation, as, for instance, square root, etc.; the principal electrical units and their meaning and theoretical circuit diagrams to figure the resistance, voltage and current of various kinds of circuits; resistances and capacitance formulas and diagrams; methods of doing by actual tests what would otherwise be perplexing; the setting up of electrical machinery, testing out faults, etc.; the operation of the motor, etc.

Such we find a set of useful alternating current formula, including the various connections of transformers.

EVEHADY PHYSICS. A laboratory manual, by John C. Packard, A. M., publisher in Sun and snow experiments, and therefore begins with elementary mechanics. The author inserts such topics as horse power, gravity, etc.

He follows up the subject of air and water measurements and considers therein the measurement of density of air, thermal capacity, etc., then the study of light, its measurements and its uses. The author treats the subject partially and in an easily understood manner. The subject on mechanics is also well written. He considers the subject of the pendulum and measurements; under "generation" the siren and vibrating strings are treated. He shows in a good way the defects of the dyes of hearing and sound therefore.

Next we find the subject of the photometer and the study of the defects problems of refraction, diffusion, etc., also defects of vision and the teeth themselves. The author includes the bio-electrical study of electricity and magnetism, and in a short space are given laboratory exercises and instructive experiments for the beginner, so that he may fully grasp the subject of electricity and magnetism.

The author is to be congratulated on being clear and concise manner, in which he treats the subjects, and for the excellent illustrations he has provided. It makes an excellent manual for high schools and similar institutions. A small order is received.

U.S. AIRPLANE
Mail Service

Started May 15, 1918

marks the real beginning of commercial aviation. Uncle Sam is carrying mail every day between New York, Washington and Philadelphia and the end of the war will make possible the extension of airplane mail delivery to all parts of the country. As fast as machines can be built they will be put to work carrying freight and passengers. But the demands of commerce must wait. Every man who knows, not merely how to make one small part of an airplane, but who has studied and learned the scientific principles of design and construction is needed RIGHT NOW to help win the war.

More Men Needed

AVIATION

Wonderful salaries are being paid to trained experts in airplane building, airplane assembling, repairing and adjusting. Here is an easy road to promotion or to a splendid paying position in the private employ of one of the scores of airplane manufacturing companies. We have more calls for men than we can supply. Never has any industry offered so many golden opportunities for ambitious men. Make it your business to investigate first before you decide. But don't wait to send for full information.

FREE

NEW BOOK—"OPPORTUNITIES IN THE AIRPLANE INDUSTRY."

Just published and mailed free on request—the first complete story of the recent remarkable development of the airplane manufacturing business and the wonderful future it holds for you. Get a copy and read it. Let your friends read it.

Mail Coupon--QUICK

No obligation of any kind. But the edition is limited. Send us your name today, before it is too late, and avoid disappointment.

BOOK REVIEW.
(Continued from page 568)

The author starts the opening chapter with the characteristics of light and with the various types of incandescent lamps. Then follows the discussion of wiring diagrams and construction of each lamp. Then comes the chapter on the subject of arc lamps, both open arc and closed, and in the same chapter he considers mercurial arc lamps. Next follows the theoretical and practical aspects of principles of illumination, where he considers the advantages of equal light distribution, candle-power, curves, non-reflecting materials,午后 artificial light, etc. Good reasons are given for the use of various types of reflectors, and the frequent use of lighting fixtures are presented in a very complete manner. The author presents practical methods of calculating interior illumination is commendable, and the author gives examples of various methods of illumination, including outdoor lighting.

In the second part of the book, the author gives the wiring of motors, and connections for direct and alternating current motors. The author gives the wiring diagrams for interpole motors, squirrel cage induction motors, and rotating motors, as well as the single-phase induction motors, self-starting synchronous motors, and synchronous motors. The chapter on selecting motors for industrial purposes is important, and the author shows how a specific type of motor is necessary to properly operate each style of machine. In this chapter the author also gives a clear description of the different types of motors as used for various industrial purposes.

Section three is devoted to the system of wiring for D.C. and A.C. and the subjects of insulation and wiring are taken up in detail. Calculations and uses of different types of wires and cables, switches, circuit-breakers and fuses are well presented. The author takes up in the same chapter the subject of switchboard installations, and in this chapter, he shows the layout of the wiring for an office, and the other a simple wiring chart for direct current circuits. By means of this chart, the author is able to solve quickly the problem of the conductor necessary to carry a particular load. An appendix contains a number of tables which are very good for the general electrician, and which facilitates the calculation of electric circuits and allied problems.

RADIO COMMUNICATION, by John Mills, 5 x 7 5/16 inches. Price, $1.75 net, published by McGraw-Hill Book Co. 206 pages, 126 illustrations, including diagrams. Imitation red, flexileather. This book was written for the purpose of instructing army and navy men, especially officers who are being prepared for the Signal Corps of the United States Army. The author has written the subject of radio communication in a very peculiar manner. The beginning of the book gives us some elementary considerations of electricity, treated in such a way as to bring the subject into the subject of alternating currents and therem-in, certain applications. It seems rather unusual that at the very beginning he should delve immediately into the subject of imaginary quantities, which very few engineers utilize, as such a subject of imaginary quantities is used mostly in the advanced study of alternating currents.

It would certainly be of greater ease to the average student of Radio Communication if the author had treated the subject of alternating currents in a more simple manner than he has done, the author believes. The book contains a double set of subjects which he has handled at the beginning of his book, and are of great value to the electronics and to radio engineers in general.

In the second part of the book, the author treats on a very important subject—the transmission of sound. The author has at least done himself justice in treating the telephone receiver in a really excellent manner. Here he gives a complete theory and explanation of the various types of receivers that have been invented. In a lucid manner he describes the various functions of the parts of the telephone receiver, including "impedance." A very good chapter on the vacuum tube is also given. In this chapter the author begins with the elementary consideration of the electron, and from there proceeds up the subject of vacuum tubes, and he then takes on the two electrode-vacuum tube and treats on the characteristics of the plate with respect to the filament. The three-element tube is ably discussed and a short description of the characteristics of this tube are given, but none of high

Just what you need to know to succeed in ELECTRICITY

Everything electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your every day work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain every day language—no wasted words—only what you need to know—check full of up-to-the-minute electrical knowledge.

The guides are a complete course in electrical engineering. They will help you in every detail of your electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handily bound in flexible black covers. You can carry each volume with you until you have found the exact information for which you are looking. They contain 300 pages and 4,700 illustrations. Once you see these books and use them, you will want to have them always handy. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over and see if the questions you can think of—are answered in them. In your work—study them—pick up some new information that will increase your earning ability. We will ship you the entire set of 13 volumes entirely FREE.

This is a sign of our confidence in our guides. Your gold does not object to being tested. Keep them for seven days and if you do not believe that you can't do without them, return them to us and owe us nothing.

When you decide to keep them for only half to one or two months, send us $1.00 down and remit the balance of $4.00 on the easy payment of 12.50 a month till paid for. Use this coupon to get the books. It will pay you many times over.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
in this case being two steel plates. The joint is usually prepared by beveling the edges of the pieces to be welded together. The other side of the electric circuit is connected to the hand electrode which is provided with a ground lead. This welding tool connects with a heavy flexible cable leading to the current supply circuit. By touching the electrode to the metal, and material a heavy arc is drawn, and to reduce the blinding glare from the arc the operator wears a head shield fitted with special glasses. The slotted arc welder draws an arc at several points along the seam to be welded, and then establishes several distinct tack welds, which serve to hold the plates firmly in line. He then proceeds to weld the entire seam, moving the electrode from side to side of the groove and giving it a semi-circular motion, while at the same time he slowly moves the electrode along the groove.

The accompanying illustration shows an excellent sample of arc welding between two plates, done by a practically new process, whereby such a weld is formed of the basic metal composing the plates; thus the weld is invariably as strong as the plates themselves.

It is important that the arc shall "bite" into the shank metal, creating a perfect fusion along the edges, while the movement of the electrode is necessary for the removal of any mechanical impurities which may be deposited. In the coated electrode it is further necessary that the slag which forms for the protection of the pure metal be blown up to the surface, and it is extremely important in the event of a second or third layer that the slag or impurities be carefully scoured away before the virgin metal is again laid on. The operation in arc welding is protected, with a screen covering his face with special glass thru which to observe his work. The electric arc emits dangerous invisible rays in both the upper and lower spectrum scale and it is quite evident that both the infra-red and ultra-violet are dangerous in their effect; the former is pathological, the latter actinic.

The operator further uses gloves for his hands and for the very difficult work of overhead welding, it is necessary for him to use a helmet which covers his breast. Without entering into an elaborate analysis of the relative costs of electric welding, it may be broadly stated that there is hardly any question that the electric process is cheaper than any other. The same may be said as regards reduction of labor and also reduction of man power. In a recent discussion of this subject by an authority it was stated that at one of the most important plants, the total number of parts on the welding program of the standard riveted ships now building at that yard amounted to 225,000. The labor cost for riveting the pieces is about $245,000, and for welding about $99,000, thus making a saving of $146,000. But this is only a mere drop in the bucket when compared to what might be profitably done in this line. The expert stated further that in certain particular instances the saving is as great as 50 per cent. The electric arc requires a reduced voltage and this is difficult to attain with direct current, without relatively expensive machinery for a useless expenditure of energy. The practise in this country in manufacturing establishments of any size has been toward an increase in the supply voltage so that very few large manufacturing plants use less than 220 volts direct current. With this voltage the only economical method of transformation is in the use of a motor-generator set. The efficiency in this case is in the neighborhood of fifty to sixty per cent. It is possible to use a supply voltage of 110 volts with a variable resistance which cuts down the voltage to the arc volts. This gives a very poor efficiency. In the case of creating current the supply voltage can be reduced by a transformer which will supply, as in the case of direct current, a sufficient voltage for striking the arc and a satisfactory reduction when the arc has been struck. On the other hand, if a low voltage alternating current is provided, a small reactance may be introduced which has a few of the same wasteful characteristics of the resistance used with the direct current. The average apparatus will permit of electric arc welding consuming about six to eight kilowatts per welder, but if low voltage is provided, these are certain outfits which will reduce the consumption to as low as three and one-half kilowatts per welder, or even less.

Regarding the spot welding of fabricated steel ships, it may be said that experiments were conducted by the Electric Welding Committee, which showed that it was difficult to weld one-half and three-quarter inch steel plates as well as one-inch steel plates; and in fact experiments were successful in welding three thicknesses of one inch steel plate. Lately, large sized spot welders, having jaws five to six feet long have been designed, and these will be used in building a spot welded steel vessel at the New York Shipbuilding Corporation, located at Kearny, N. J., which represents the largest portable spot welder ever completed. The spot welder has five feet and, considering the five foot jaw spot welder with multiple contacts spaced at a distance corresponding to the oldtime rivet, one is actually astonished when stopping to consider...
LEARN PUBLIC SPEAKING

10 LESSONS FREE

Write—quick—for particulars of this extraordinary offer; an opportunity you will never forget if you take advantage of it. Ten lessons in effective public speaking absolutely FREE to those who act promptly, to introduce our course in localities where it is not already known.

WHAT THE COURSE TEACHES YOU

How to talk before your club or lodge.
How to address board meetings.
How to prepare and respond to toasts.
How to make a political speech.
How to tell entertaining stories.
How to make after-dinner speeches.
How to converse interestingly.
How to write better letters.
How to sell more goods.
How to train your memory.
How to enlarge your vocabulary.
How to develop self-confidence.
How to acquire a winning personality.
How to strengthen your will power and ambition.
How to become a clear, accurate thinker.
How to develop your power of concentration.
How to be the master of any situation.

We Teach You By Mail

We teach you by mail to become a powerful and convincing speaker—to influence and dominate the decisions of one man or an audience of a thousand. We have trained hundreds and helped them to increase their earnings and their popularity. Learn in your spare time at home how to overcome "stage fright" and conquer fear of others; how to enlarge your vocabulary; how to develop self-confidence and the qualities of leadership; how to RULE others by the power of your speech alone; how to train your memory. Our

NEW, EASY METHOD

perfected and taught only by Prof. R. E. Pattison Kline, former dean of the Public Speaking Department of the Columbia College of Expression, can be learned in 15 minutes a day. Prof. Kline is one of the foremost authorities in the country on public speaking and mental development. Do not let this chance escape you.

HOW SHIPS ARE WELDED BY ELECTRICITY.

(Continued from page 572)

Consider how much time and labor of efficiency is occasioned by the old method of riveting steel plates and girders, where but one rivet can be handled at a time. Think of a six foot gap electric spot welder which can then accomplish a seam in the construction of radio apparatus. Here are found the need and importance of this method, and in each case the author works out an example for the student, so that he can familiarize himself with the method of working such a problem.

BOOK REVIEW.

(Continued from page 570)

Frequency currents, and as an amplifier. In the next chapter we find various types of detectors of high frequency currents, and detectors. As a practical application of undamped high frequency oscillations is also commendable. A short discussion follows on the chapter on Radio-telephony. In the eighth chapter the book gives several devices for the construction of radio apparatus. Here are found the need and importance of this method, and in each case the author works out an example for the student, so that he can familiarize himself with the method of working such a problem.

PRACTICAL ELECTRICITY. by Terrel Croft. Cloth bound, 560 pages, numerous illustrations, size 5½ x 8½ inches. Price $2.50.

Another excellent work from the author of mechanical books on the subject, it has been arranged in 53 elaborately illustrated chapters, with all the matter arranged in proper sequence.

The author states that the object of the book is to present the fundamental facts and theories relating to electricity and its present-day applications, Isaacs and Smith's W. H. New York, 1917. Price $2.50.

Another excellent work from the author of mechanical books on the subject, it has been arranged in 53 elaborately illustrated chapters, with all the matter arranged in proper sequence.

No higher mathematics have been indulged in, with no loss to the value of the work; the numerous and readily visualized analogies, which the author is adept in supplying, are a great help.

A study of the book will find it a valuable aid to all, whether teacher, student, practical worker or layman. It is invaluable to the boys who have been working the coals from the mind and to reform and recondition in line with modern electrical theory and practice.

The author has endeavored to put forth in a clear and concise manner the theory and operation of Direct Current Machinery, without aid of higher mathematics, although some mathematics of elementary nature has been used here and there. Magnets, and electromagnets, and the unit of suggested work, have been especially dealt with in order that the student should obtain a clear understanding of the principles of dynamos and motors. The book further shows that whenever energy is transformed by a man-made mechanism to electrical or vice versa, that a loss is made, and it is true in this regard giving the efficiency of a motor or a generator.

The various types of motors, dynamos, including direct-current, alternating, and d-c motors, are all given. Armatures of the drum, disc, lap, wave, and other types are fully explained, including the various capabilities of each, accompanied by numerous red and black line charts which serve to corollary clearly the various methods of wiring armatures. The uses of electrical energy, or the advantages of the three-wire system, types of dynamos and motors—INCLUDING their operating characteristics—is of course, a chapter on the "Selection and Installation of Dynamos," are additional features of this book. In general, this book is designed to assist to students, engineers and electricians, and all those who have occasion to deal with Continuous Current Machinery and its allied problems.

TELEGRAPH PICTURES

This unique set of improved, Leashman's Picture Telegraphing Machines will telegraph pictures, maps, drawings, and hand writing. The invention of the Leashman systems recently telegraphed a picture of President Wilson as far as from Paris to Chicago.

L. J. Leishman Co.,
Dept. T.
Ogden, Utah

ACTIVE SERVICE

$1.25

J. R. Ullrich & Co., 27 Thames St., New York

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.

An excellent treatise on the subject of direct current motors and the practical applications there of, with numerous illustrations of up-to-date machinery.

This book is intended for the student, the owner of D.C. machines, the consulting engineer, the motor inspector, and supervising engineer, for the man who will subsequently have charge of the machine and for the civil or mechanical engineer who desires to have some knowledge of the subject.

There are several chapters in this book which divide the subject into many parts, such as the elementary theory underlying the action of motors, the starting of motors that have once been started and stopped; the variation of speed and the reversal of the direction of the motor, etc. Still further on the book treats to some extent with the theory of D.C. motors, especially matters so that more speed and power, and several types of central station apparatus, including automatic and semi-automatic appliances. The efficiency of motors and the various methods of determining the amount of power of the various kinds of motors and central station apparatus, are also fully described.

For each chapter there is given a set of examples and answers which should prove of immense interest to all. The appendix shows how to determine the resistance step for use in starting a motor, how to use Logarithms, and how to connect a motor on higher or lower voltage than that for which it is rated. In short, the book is a complete treatise on D.C. motors, the various appliances used therewith, the practical application of the subject and a textbook for the library of those who have occasion to use or install Continuous Current Motors.

Part II of this work proves to be a useful handbook and one that will be popular as a reference book. The editor and his contributors have been瓶子 generally in this special branch of electrical science. Still further on the book treats to some extent with the theory of D.C. motors, especially matters so that more speed and power, and several types of central station apparatus, are also fully described.

The following list of contents should prove of interest: Curves, diagrams and their meaning—the logarithmic, parabolic and hyperbolic curves, the sine curve, etc.; the theory of direct current systems; direct current dynamics—the pressure and its adjustment and measurement; the eddy currents and their effects—how they are overcome; the A.C. transformer, the action of the windings, the electrical analog of the transformer, inductance of transformers, and the relations between the current and voltage in tuned circuits, with mechanical analogs of various A.C. circuit relations, such as effect of capacity on phase relation; the effect of inductance on phase relation; effect of resonance; etc. The logarithmic over and under excitation of transformers are well written and of great benefit to all radio workers. Spark discharges are treated in detail. A very thorough chapter is devoted to "cancellation valves"—governing, "best and erection of undamped wave signals, reception of weak signals, etc. This section on valves is quite complete and treats on the theory of the Fleming two- and three-pole valves. De Forest, Armstrong and Langmuir are unknown quantities to this author apparently.

A valuable book to all interested in the art, and dealing with the subject of Radio in a simple and clear cut manner. This book takes us into the inner technical problems involved. It treats the problems more interesting and more important in less books dealing with the subject.

DO MAGNETS MAKE PHOTOGRAPHS?

The 1917 Year Book of the Carnegie Institution of Washington, D. C., has the following interesting "magnetophotography" experiments conducted by L. A. Bauer and W. F. G. Swann:

A large number of experiments have been performed and some are practicable to give more than a general survey of the work. In all of the experiments in which articles with a metallic field, a subsidiary plate was set up and the experiment performed to some influence of a magnetic field.

December, 1918

ELECTRICAL EXPERIMENTER

Your big chance to Learn Mechanical Drawing

at home as you would at our school

THERE is a very great shortage of draftsmen in the industries and government departments of this country. The shortage is so great that the situation is serious. Draftsmanship always one of the best professions. What is it now? It has become of such importance the very progress of Industrial America depends upon it, and both men and women are earning from $35 up to $100 per week. This great demand for a draftsmanship, in war and peace, will probably never be satisfied.

A

S soon as you begin our course, you start on actual drawing work. You do not waste any time with needless theory and preparation. You become a draftsman at once, and remain in actual practice until you are a master draftsman. We are in touch with the great shops of the country and the various government departments. We know their needs, and teach you accordingly. There is a great demand for Columbia School of Drafting students, because it is well known that these students are TRAINED, PRACTICAL DRAFTSMEN, and can step into actual work.

Mechanical Drawing one of the shortest possible routes to big pay

intended, production manager, efficiency engineer and master draftsman, in war and peace, be earning up to $10,000 a year and over, owe their success to their knowledge of mechanical drafting and draftsmanship.

The Columbia School of Drafting is one of the finest and best institutions of its kind in America.

The large building situated at 14th and T Streets, N. W., Washington, D. C., is entirely occupied by the Columbia School of Drafting. It is a large and well-lighted building taken by Mechanical Drafting. The same thorough instruction is given our Home Study pupils, by correspondence. Our Chief Instructor and President, Mr. Claflin, personally looks out after the training of each student. Our course is designed to make of every man or woman who enrolls a master draftsman.

No Previous Training Necessary

As our students are put into actual practice at the beginning, they grasp the essentials of drawing quickly. The lessons supplied are so clear that even the backward students can understand them. No previous experience nor special education is necessary.

Return the Coupon Today — It Brings to You a Valuable Book — FREE

Your future depends upon what you do now. We cannot teach to all who hope to succeed in the draftsmanship profession. This is the only course in up-to-date Mechanical Drawing. If you are interested and desire to learn a big paying profession, at reasonable cost, we urge you to act now, by returning the coupon at the right. We will immediately send you our Free Book. It tells of our new methods of teaching mechanical drawing, andoutline our offer to you fully.

COLUMBIA SCHOOL OF DRAFTING

Dept. 956, 14th and T Sts., N. W., Washington, D. C.

Without obligation to me, please send me your illustrated book, "The Draftsmanship Lesson" telling how I can secure your complete Home Study Course, the DRAWING OUTFIT, and your help in securing a position as Draftsman.

Name

Address

City State
"Uncle Sam" needs thousands of operators and is calling for more all the time. Here is your chance to become an expert telegrapher at a small cost. The practice outfit shown here is exactly the same as used by the United States Signal Corps and comprises the following: A highly polished mahogany finished wood base, a real high frequency buzzer giving a high note, with nickel-plated case, regulation nickel-plated steel lever key. Also brass etched plate showing the three international codes mounted on the base for quick practice. A new feature not found on any other set, you simply cannot miss this code. This outfit quickly gives you speed, and enables you to learn telegraphy, Morse or wireless code in a short time. Special attention is called to the buzzer which gives a clear high note, not a rattling noise as many inferior outfits now on the market. IMMEDIATE DELIVERY. We ship the same day that order is received. Your money refunded if you are not satisfied.

Price as Illustrated.

Shipping weight 2 lbs.

Size over all 8 x 2 x 7 1/2 in.

THE TEWNO CO.

150 Chambers St., New York

CORE WIRE—20c lb.

We have been fortunate in securing thru auction several tons of guaranteed pure, double annealed Norway Iron Core Wire and are selling this wire to "Experimental" readers only at this price. This wire is just the thing for spark coils, transformers, etc., and it is, of course, a very much more superior product than the usual iron wire. We absolutely guarantee the quality.

If you ever thought of building a spark coil, transformer, or similar apparatus, now is the chance to get the right material for it. As far as we know this is the only lot of iron Norway Core Wire in the hands of any dealer at the present time, and none can be gotten until after the war.

We have only two sizes left:

26 INCHES

36 INCHES

Thickness about No. 21 B and S

If either of these sizes should be too long we advise cutting the wire down yourself by means of shears. It will pay you to do so as real Norway Iron Wire, sold by a few dealers last year, brought from 50c to $1 a pound. American core wire now sells for from 35c upwards per pound.

ELECTRO IMPORTING CO., 231 Fulton St., New York City

Important Announcement from Washington, D. C.

The Government of the United States has found it necessary to ask every householder in the Nation's Capital to offer their spare rooms to those brought here for war service. Thousands of young women from the best American families will in this way find suitable homes.

In order to meet war conditions the DEWEY HOTEL, situated in that exclusive residential section, at 14th and L Streets (5 minutes' walk from the White House), has opened its doors to transient guests. For many years the Dewey has been the official residence of Senators and those prominent in official life of the Capital. The accommodations are limited, and only those whose presence will be compatible with its clientele will be accepted. It will be best to make reservations by letter. Room tariffs, illustrated brochure, restaurant charges and other information may be secured by writing.

FRANK P. FENWICK

with a similar set of articles, but beyond the influence of the magnetic field. In the earlier experiments, this subsidiary plate was placed in an ordinary plate-box at atmospheric pressure, the box being bound around with dark cloth; but in the later experiments it was placed in the same vacuum as the main plate, and shielded from the magnet by an iron disk. All experiments except the last two were performed with limited darkness, the photographic red light only being turned on after the articles had been mounted in the bell-jar, and the latter had been bound around with dark cloth.*

In order to test whether the effects observed could be attributed to radio-active material, two experiments were made with permanent magnets, but in the case of one of them the bell-jar was washed out with a weak solution of uranium nitrate and allowed to dry. After an exposure of 21 days, the articles showed up equally strongly on both plates.

A plate was exposed for 6 days over an electromagnet, the articles being pieces of wood, iron, copper, amber, and cork; also, in addition, a piece of wood resting on a piece of metal which was in contact with the plate, and a piece of lead resting on a piece of wood which was in contact with the plate. Both pieces of wood in contact with the plate showed up dark on a lighter ground, the grain of the wood being very clear, and the cork showed up slightly darker than the ground. The metals in contact with the plate came out lighter than the ground. In the case of the subsidiary plate which was set up at atmospheric pressure, only the amber showed up, and this appeared dark on a light ground.

Several experiments made with the articles slightly separated from the plate showed that their images fell off rapidly within a distance of 1 or 2 mm.

The effect of resin in acting upon a photographic plate, especially when the resin has been previously stimulated by light, is well known, and at once suggests the assumption that the resin wood, cork, etc., produce a radiation of some kind, or a gaseous emanation, the latter being produced either directly or as a result of the radiation, and that this gas diffuses over the body of the plate and darkens it. In this case the metal articles would simply act as shields to the plate. Experiments made with stimulated resin and metallic articles showed that distinct impressions of the objects could result only provided the resin was in this way without a magnetic field or a vacuum. At atmospheric pressure the darkness of the plate falls off with the distance from the resin, but on evacuating the space around the resin the "range" of the action is increased and the impressions are much more uniform.

A large number of experiments were made with stimulated resin, and it appeared that the action was propagated roughly in a linear manner for a distance of about such as a centimeter or more, and after traversing this distance was still capable of passing thru aluminum leaf.

The apparent action of the magnetic field in the experiment with wood and metal articles suggests that a similar action should be produced in the case of the resin. If the action of the resin is ultimately attributable to the ejection of charged particles, the possibility of producing deviation by a magnetic field at once suggests itself. New marked influence of this kind was, however, found in the case of the pure resin.

* Those interested in magnet photography should refer to the original articles on this work written by Mr. Noyes, and which were set up in the October and November, 1917 issues of the Electrical Experimenter.
One of the most remarkable features of the photographic action produced in the case of wood and metal articles is that it is approximately uniform over the plate, altho the magnetic field varies both in magnitude and direction. If the action of the magnetic field were one of controlling the direction of propagation of a radiation or gaseous effusion emitted by the substances, one would expect it to vary over the surface of the plate. The absence of such variation practically limits the nature of the effect to one in which there is direct or indirect stimulation of the activity of emission or production of active gas, diffusion being subsequently relied upon for the uniform distribution of the effect over the plate.

The effect of very slight temperature changes in modifying the action of metallic articles upon a photographic plate is well known, and one has to remember that an electromagnet becomes appreciably warmed during its existence.

The presence of resinous articles does not seem wholly necessary for the production of the apparent magnetic effect. Thus, for example, a number of metal articles, namely, lead, iron, nickel, copper, and brass, were set up over an electromagnet in a vacuum for 14 days, and a similar group was set up in the same vacuum, but in a region shielded from the magnetic field. The first set produced strong impressions, light on a dark ground, while the second set produced no appreciable effect. The experiment was repeated with a permanent magnet and an exposure of 21 days, with similar but less pronounced results.

At the stage of the work recorded in the paper here abstracted, the preliminary conclusion was reached that while a magnetic field or vacuum was not essential to the production of effects of the kind recorded by Mace, the magnetic field appeared to have an effect in intensifying the action in certain cases. The experiments are being continued with the object of ascertaining whether the primary agency producing the effect, in the case of the electromagnets, for example, is really the magnetic field itself or some other influence accompanying the production of the magnetic field.

EXPERIMENTAL CHEMISTRY.

(Continued from page 538)

Properties of Sulfur (Physical).

1. It is a yellow solid, without odor or taste. 
2. It has three allotropic forms, two crystalline, and one amorphous.
3. Its color is usually lemon-yellow when solid, when finely divided it is white. It gradually becomes dark red and viscous on gradually raising the temperature from 200 to 280 degrees, when it is too thick to pour, and becomes almost black in color.
4. It is non-poisonous, and may be taken internally, as is frequently the case in the spring, when the so-called sulfur and salt licks makes its appearance as a blood purifier.
5. The so-called "sulfur odors" do not come from the element, but rather from the compounds, as Sulfur Dioxide, Hydrogen Sulfide, Carbon Disulfide.
6. It is insoluble in water, the best solvent being one of its compounds, Carbon Disulfide, in which it dissolves unchanged, tho the amorphous variety does not dissolve and flowers of sulfur only slightly.
7. It is negatively electrified by friction.
8. Sulfur melts at 115 degrees to a thin, amber-colored liquid. At 200 degrees it becomes thick and dark colored and can hardly be poured, while at 300 degrees it again liquifies. If poured into water at the amber stage, it crystallizes, but if at the latter stage, it is amorphous and elastic.

(Continued on page 579)
CHEMISTRY!

We present herewith to our friends our new E. I. Co. Chemical Laboratory which contains real chemicals and apparatus to perform real chemical experiments. This outfit is not a toy, but put up merely to amuse, but a practical laboratory set, with all the chemicals, apparatus and reagents necessary to perform real work and to teach the beginner all the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

44 Chemicals
17 Apparata
1 Instruction Book with 100 Experiments

PRICE $5.00

Shipping Weight 10 lbs
CAN BE SHIPPED BY EXPRESS ONLY

THE E. I. CO. CHEMICAL LABORATORY
DESCRIPTION OF THE OUTFIT

It contains the following 44 chemicals:

<table>
<thead>
<tr>
<th>Ammonium Chloride</th>
<th>Brimstone</th>
<th>Ferrous Sulphate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alum</td>
<td>Iron Oxide</td>
<td>Nickel Sulphate</td>

ELECTRICAL EXPERIMENTER

414 PAGES 145 ILLUSTRATIONS $1 ELECTRICITY!

HERE’S just the book on Electricity that you need to answer your many questions—to solve your knotty problems, to teach you new tricks, to be your memory for tables, rules, formulas, abbreviations, and other useful data that you must know to handle Electrical and Mechanical facts that some people try to sell to you at a high price.

With this “Little Giant” I. C. S. Electrical Engineer’s Handbook in your pocket, you can run your work bench, drawing table or desk, an hour or a day, not feel lost “figuring up” some forgotten rule, some unfamiliar fact; you’ll just turn to the very complete index and get it “in a jiffy.” Just a few of the subjects treated are:

Electricity and Magnetism: Electrical Symbols; Batteries; Circuits; Magnets; Direct and Alternating Currents; Transformers; Alternating Currents; Magnetic and Electrical Measurements; Motors; Arc and Incandescent Lamps; Mercury Arc; Transformer Diagrams; Insulation; Electric Cars; Single and Multiple-Unit Control; Transmission Lines; Tables of Wires—Sheaths, Capacities, etc. —Mathematical Formulas—Summary of the Laws of Constants, Equivalents, Roots, Powers, Resistance, Induction, Areas, and Arcs—Use of the Ohm—Chemistry; Properties of Metals; Principles of Mechanism; First Aid, etc.

The Electrical Engineer’s Handbook is one of 22 I. C. S. Handbooks covering 27 Technical, Scientific and Commercial Handbooks, sold as a set.

They have the contents of a full-size book compacted into pocket-size ready to go with you anywhere and anytime. For some, the book in itself is a valuable item, a ready reference. For others, a ready reference; for others, an aid to memory. You can count on the pages of this book to be comprehensive in the important facts and figures that you are likely to need in your work. Simply send a letter for your copy now. I. C. S. can make your money refunded if at any time within the first thirty days you wish to return the book, your money will be refunded.

MUSIC TAUGHT FREE

You can learn to play the violin. A free booklet tells you how to get started right away. Three Schools already have received over 200,000 requests for information.

AMERICAN SCHOOL OF MUSIC, 57 Lakeside Bldg., Chicago.
PATENT ADVICE

In this Department we publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Regular inquiries addressed to "Patent Advice" cannot be answered by mail free of charge. Such inquiries are publish here for the benefit of all readers. If the idea is thought of be of importance, we make it a rule not to divulge all details, in order to protect the inventor as far as it is possible to do so. Should advice be desired the mail charge of $1.00 is made for each question. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

Readers' attention is called to the fact that due to the great amount of letters to this department it is quite impossible to answer them all through these columns. The inquiries answered in this issue date as far back as June, and if readers wish speedy service they should carefully, fully note the announcement appearing in the preceding paragraph.

Arc Lamp.

(279) William Woodward, of Wilmette, Ill., submits an idea of a self-regulating arc for moving pictures which he would like to have our opinion on. He says "let us presume that the operator strikes the arc and adjust it. In a few minutes the carbons would be too far apart, but for the feeder which pushes carbon up as follows: When the current diminishes, that is, the carbons draw apart, the brass rod C becomes cool and contracts, which by a lever of the first class pulls the carbon up. When there is a demand for current, the action is vice versa. Of course, about half an hour it would be necessary for the operator to screw the carbons up for continued use. The horizontal adjustment would be adjusted as on a modern machine."

A. An extremely clever idea as well as capital idea. It is doubtless the most economical and light regulating scheme ever to be used. If it works out as promised, it will save the expense of the horizontal adjustment.

B. If this idea is in practice as well as it looks on paper, we think that our correspondent has a very valuable patent. Our advice is to get busy at once and build a model and apply for patents in the meantime.

Swaying Screen Door.

(260) C. L. Emmons, St. Joseph, Mo., submitted a very clever device on a screen door which will swing open when pushed in either direction or on either side. A number of metal strips are used in order to effect this and our advice is asked.

A. This is indeed a remarkably clever idea, and the only fault we have to find with it is that the hinges would sag because the special hinges used seem to be too long, and sooner or later would cause trouble. With these, there might be found ways to overcome this objection, and we are certain that a patent can be obtained on the invention.

B. Another idea by the same writer relates to making distilled water, or drinking water from salt water. The apparatus consists of a pump to which heat is applied and a coiled metal tube, cooled in water through which the distilled water is discharged. A. There is nothing fundamentally new contained in this idea, and a patent cannot be obtained on it.

Edited by H. Gernsback

Power Jack.

(281) Cleo Maddy, Utica, Kan., sends an idea of a power jack for an automobile to be permanently secured to the rear bumper, made of copper and a small band of cold-rolled steel. The jack is operated by the starter by means of two small red and black wire. Our correspondent wishes to know if the idea has been patented, and if it is practical.

A. We are afraid that while the idea is not impossible, of course, it would be impractical for a number of technical reasons, unless simplifying improvements were made on the device. We think it has always been founded on the idea—of how much value it will be, we do not pretend to know.

Changing D. C. to A. C.

(282) Edward Huesher, New York City, encloses a diagram of a device for changing 110 D. C. current into 110 A. C. to any number of cycles desired. The idea is to have a metal spider wound with wire operated from an 110 D. C. motor, the ends of the spider cutting thru an electromagnetic field. A. This device could be taken from the spider and from the wire ends.

A. This is a clever idea, and we believe it is feasible, but we doubt if a patent can be obtained on it as very similar types are in use.

Rifle Improvement.

(283) Wilford Dooler, San Francisco, Cal., sends in a device whereby it becomes possible to equip or to have a small gun or rifle fire any size cartridge desired. A. We believe, present guns can always fire a small cartridge.

A. This is a clever idea as well as ingenious, and we think a patent may be obtained upon it. We doubt, however, that it has any practical value, as too many special inserts would be necessary in order to equip rifles that this is other than the inventions that seem very good, but have practical objections which are entirely unanswerable.

(284) We publish in full an interesting letter by one of our readers, J. B. Warren, Kearney, N. Y.,

"I notice in the July issue of the Electrical Experimenter that you have inaugurated a new feature in one of your most valuable departments, the 'Patent Advice' department, whereby you will disclose the invention freely to the public, sent to you, and publish it in the department. I have just read this, and I think it is an excellent idea. I have been experimenting with an invention of my own for a long time, and I think it is worth while to get a patent on it. I would like to have you publish this invention, and I would like to have you write me a letter telling me how to do it."

Our facilities for securing patents enable us to give prompt and efficient service at reasonable rates. Inventors are invited to write to the following questions appearing in this department protecting all matters receive prompt attention. Send for blank form of disclosure to prevent your idea from going lost. It will pay to place your patent in the Patents Office. Book of Instructions and blank forms are free on request.

A. M. Buck & Co.

206 Second National Bank Bldg., Washington, D. C.
ELECTRICAL EXPERIMENTER

100 Tenth Avenue, New York City

December, 1918

Knob K. Our advice is asked on this arrangement. A. This strikes us as an excellent idea and certainly a patent can be obtained on the idea. We suggest that our correspondent get in touch with patent attorney at once.

This correspondent also submits a diagram on an electrical horse for cars operating on the vibrating diaphragm principle. Our advice is asked.

A. There is nothing new about this device, there being on the market several automobiles built working on this principle.

Phonograph Motor.

(287) Floyd Hoskins, Fine Bluff, Ark., submits an idea on an electric motor concealed in the inside of a phonograph, driven by dry cells, thus driving the phonograph disc. Our advice is asked on the arrangement.

A. This is quite an old idea and nothing of this sort can be patented, many motors being used accomplishing exactly what our correspondent describes.

Sound Electric Shutter.

(288) Emison Furrell, Higgivsville, Mo., wishes to have our advice as to patentability of a sound electric shutter operating device for a camera. When the person standing in front of this camera says "Hello," the sound waves strike a microphone which in turn allows a current to pass thru a highly sensitive relay. An armature is then pulled over, making contact, while the current from the battery passes thru an electromagnet and the magnetism induced therein pulls over an armature which in turn snaps a shutter or finger. One does not have to be a photographer to active this device. The entire device, of course, has to be made up and a camera placed in it. Not alone could this be accomplished, but the film could be utilized for taking close up pictures of explosions, for secret service work, and for novelty use taking of unexpected pictures of friends.

A. This is a really capital idea, and while the idea itself is not fundamentally new, we are certain a patent can be obtained on it in the combination with a phonographic camera. While, of course, such a sound operated device is not new, there being on the market at present a toy dog which comes out of his house when a whistle is blown, the combination of a sound operated camera shutter presents great possibilities. We would advise our correspondent to obtain a patent on this idea.

Naval Consulting Board.

(289) Percy F. Walsh, Keyser, W. Va., claims to have invented a device which by means of a few big guns he claims he could not have to patent it; he would rather give it to the government for free. We refer our correspondent to the Navy Department and the Patent Office. Our advice is asked.

A. It is not practical to address an individual of government department or office and ask them to turn over any patent. He wished to address it to a certain individual of such a department. Our advice is asked.

Detectors.

(286) Homer Surbeck, Rapid City, S. D., submits a wireless detector which consists of a metal wheel with a number of cat whiskers mounted on the periphery of the wheel. We refer our correspondent to the Patent Office and the Patent Examiner. Our advice is asked.

A. It is not practical to address a government department or office and ask them to turn over any patent. He wished to address it to a certain individual of such a department. Our advice is asked.

ELECTRICAL GOODS FOREIGNERS NEED.

There is on display at the Bureau of Foreign and Domestic Commerce, at the New York Custom House, Battery Place, a large technical collection of samples of electrical goods used in foreign countries.

It includes wiring devices, heating appliances, electrical porcelain, dry cells, flashlights, electric bells, conduit and conduit fittings, insulated wire, etc.

These samples have been forwarded mainly in connection with the several inves
tigations undertaken in South America by P. S. Smith, and in Australia, New Zealand, Japan, and eastern Siberia by R. A. Lundquist, special agents of the Bureau. Complete data accompany each article on exhibit, giving country of origin, where, when, and how they are selling price, etc. There are several hundred items in the exhibit.

There is a wide field abroad for standard American electrical goods, as well as for adaptations of American designs to foreign requirements, and when our electrical manufacturers study the types of goods now in use in each market, they may obtain a grasp of the standards and of the conditions existing that can be secured in no other way, as the industrial visit, to the field, and this knowledge will enable them to push the sale of their goods with the best possible efficiency.

EXPERIMENTAL CHEMISTRY.

(Continued from page 599)

Uses.

It is used mainly in making sulfuric acid. Bleachers of silks, woollens, and straw goods employ it, but it is not used on cotton goods.

It is sometimes used as a disinfectant. Sulfur being burned in a room occupied by persons having an infectious disease, the room being tightly closed, the sulfur dioxide from the burning sulfur will kill all disease germs. Formaldehyde (Formalin) is, however, becoming quite generally used in place of the sulfur dioxide for this purpose.

Experiment No. 140

Forms of Sulfur.

Fill a test tube one-third full of pieces of brimstone and heat slowly. Note the fluidity of the liquid formed. Continue the heating until it becomes almost solid, then note any further change on more heating. Notice color changes at each stage. Finally pour some of the contents of the tube into a dish of cold water. Pull that portion and observe its elasticity and amorphic nature. Let it cool, stand and see whether it remains its original state. Be on the alert for crystallization.

Experiment No. 141

Compounds of Sulfur. Hydrogen Sulfide.

Prepare a generator of about 125 or 250 cc. capacity and fit with a two-hole stopper. Into this put about 5 grams of Ferrous Sulfide (FeS), about 20 cc. of water, and at first about 1 cc. of hydrochloric acid, which amount may be increased from time to time as necessary.

First collect some of this gas by downward displacement in a wide-mouthed bottle (See Fig. 149). Note the color, and apply the splint test for combustion. Test the solubility of the gas by passing some into and over litmus paper (See Fig. 150).

This test with (a) Litmus paper.
(b) By putting a drop of silver nitrate, or (c) By pouring a little into a solution of Lead Nitrate.
(d) By holding over the mouth of the tube a paper wet with a drop of lead acetate solution, and warming the tube while making
Learn Shorthand that Quick

No longer is it necessary to spend months of time studying shorthand. You can master all the lessons in K. I. Shorthand at home in five evenings. Don't doubt this amazing truth! Send for free lessons also convincing proof that this is the simplest, most practical, lowest-cost course in stenography by personal correspondence instruction.

On 30 Days' Approval

Everyone needs K. I. Shorthand—those in business and the professions for their personal ready use and as a valuable aid to their employers. We have found that skilled operators would save compared to the amount of effort and expense not necessary to acquire it, it will help you record previous ideas instantly—do your paperwork for you—develop your all-round efficiency tremendously.

If you are going to be a stenographer, learn K. I. Shorthand because it will fit you to the work you have before you. Learn shorthand to enable you for the highest positions. Learn shorthand to enable you to compete in the lowest-cost, highest-pay positions. Learn shorthand to enable you to compete in the lowest-cost, highest-pay positions.

Free Lessons—Send no Money

K. I. Shorthand is offered on the most liberal terms right now. Do not miss this opportunity. Send immediately for the first two lessons free. You may then continue the entire course at your option at a small fee. You may then continue the entire course at your option at a small fee. We shall send no lessons. ELECTRICAL EXPERIMENTER

December, 1918

Afternoon and Evening Classes
under competent instructors. These courses are given for those who wish to qualify for a regular appointment, or for self-improvement.

Wireless Department
under personal supervision of E. E. Buscher, Instructing Engineer, Marconi Wireless Telegraph Company. This department is exclusively for military, naval and draft men. Complete courses for commercial operators, also Radio Engineering Problems.

Land-Line Department
superintended by G. E. Fleming, Chief Operator, Western Union Telegraph Co.

The Y. M. C. A. Telegraph School offers instruction at lowest cost. Ideal living quarters for out-of-town students. A licensed department to the Army for temporary employment for students who must earn while they learn.

Wire for illustrated folder and full particulars.

ELECTRICAL EXPERIMENTER

Be A Boy Chemist! Get A Complete Chemical Laboratory for Christmas
Test your drinking water, your food, the earth in your backyard, and other things you use and wear. Make soap, ink, dye, free-proof cloth and wood, and work hundreds of other useful, fascinating chemical experiments just like a real chemist. Perform wonderful tricks of mental magic and mystify your friends. You can work these and many more experiments with "CHEMCRAFT"—the Boy's Chemical Laboratory.

"CHEMCRAFT" Absolutely Harmless—No Dangerous, Explosive or Poisonous Chemicals. Complies with all State laws regarding sale of poisons and explosives. Outfits contain all chemicals and supplies to perform each experiment many times. Also Manual of Instruction: written by a practical chemist and scientifically correct.

CHEMCRAFT No. 1—$1.25 West of Mississippi River and In Canada—$1.50
CheMCRAT No. 2—$2.50 West of Mississippi River and In Canada—$3.00
CheMCRAT No. 3—$3.50 West of Mississippi River and In Canada—$4.00

Be sure you get "CHEMCRAFT," the original and complete and complete chemical outfit. Ask for it by name at your Toy Store, or send three cents to the address given below. Write for more information.

Hagerstown, Maryland

3,000,000 FISH AN HOUR WITHOUT A HOOK

(Continued from page 528)

sacred angling grounds. That was the time that you were angry, if you ever were in your life. The same principle seems to apply. If you add a little carbon disulphide to the dish, and if the sulfur dissolves, either eat the dish in a draft of air or blow across the liquid, and look for the formation of crystals. This is a very common and should be carefully described. What evaporates, the carbon disulphide or the sulfur, or both? Is it then apparently a physical phenomenon? Or is the sulfur in the liquid, when is it thrown out, does it occur in the crystalline or the amorphous state? Of what other element have you found carbon dissolving a solvent? What is the natural state of these two elements of which this compound is composed?

(To be concluded)

3,000,000 FISH AN HOUR WITHOUT A HOOK

(New Yankee Inventions. Continued from page 530)

interval, so as to scatter the bombs over a wide area. The torpedo is propelled by compressed air or other form of energy, and the equilibrium is modified by a swinging pendulum hung within the shell, and which is connected by suitable cables to the rudder and elevating planes.

The inventor claims that the machine is capable of traveling at a high rate of speed over a considerable distance—much farther than is possible to fire ordinary projectiles —and it is intended that a very large number of the torpedoes be launched simultaneously, the entire array being cleared on a broad front and to a considerable depth for infantry charges, etc. By electrical or other means the mechanism inside is arrested in the event of the machine to maintain the balance, and as soon as they are dropped the equilibrium of the machine is destroyed, the nose or front end becomes heavy causing the machine downward. The shell contains an explosive charge so that when it strikes the ground the charge, in being detonated, will blow the machine to atoms, preventing it from being used by the enemy—destroy-

The final patent here illustrated is that awarded to John B. Felicetti, a Philadelphian, and an inventor with true Italian ingenuity and originality. We have had one-man tanks and one-man submarines, but this one-man self-propelled tank is about the best device in this branch of military inventions that we have come across for some time. As the illustration indicates, the operator lies prone inside the tank, and the whole body is protected by the steel armor. When desired he can also sit up in the tank. The inventor claims that this tank is sufficiently light so that it may be carried when necessary over short distances by the operator. The Signal Corps should find a device of this kind very useful, for an observer could safely advance quite a distance beyond the front line observation points, with a well camouflaged steel tank of this description. It is propelled by the operator pulling on the two handles shown, which actuate two steel spades on the rear of the machine and which dig into the ground alternately. The steering is accomplished by means of the feet. The inventor ambitiously points out that his tank can travel over land, sea, snow and sand, or thru water and mud. In order to be able to negotiate ponds, brooks, and the like, the vehicle is provided with broad flanged wheels, and the axles are not brought out on a line with the wheel hubs, but extended upward behind the wheels before they enter the tank housing. The reciprocating levers actuating the two spades which propel the vehicle slide in water-tight stuffing boxes. When operated thru water, the steel spades at the rear act as oars or paddles. Imagine what a flock of these one-man tanks, all decked out in their camouflage war-paint would look like as they swept up over a hill on a charge.

THE CODE-NUMERALS GET THEIRS.

(Continued from page 549)

... = "N"  
... = "D"  
... = "Y"  
... = "V"  
... = "3"  

Imagine writing: "Would not consider offering 925:3 to a man if not satisfied," and having it delivered "Would not consider offering you nut; may go to Dav-ll. if not satisfied." Some business has to be declined, of course; but a declination in a form like that would be considered abrupt, if not actually rude. Well, then, if the "abbreviated" numerals can avoid such pitfalls, why need our little dots shake in their little shoes?

Finally, brethren (as you reach for your hat under the pew), behold the number 128,035, expressed in the four different ways we have considered:

1. with the digits spelled out:
   
2. in the official numerals:
   
3. in the abbreviated numerals:
   
4. in plain dots:
   
Try it on your "buzzerola". And now, Human Nature, let the blow fall!
### Learn Aviation Mechanics

“Supremacy in the air is the key to Victory!”

Train yourself for the Aviation Service by availing yourself of the Preparatory Ground Courses in Airplanes Mechanics, approved for pilot training prior to entering Government Ground Courses, covering aerodynamics, aero-engineering, flying and Lewis gunnery. Previous experience unnecessary.

- **Complete Course**: Including 6 weeks of aero-engine course, taken in six weeks (three hours daily) or three weeks (six hours daily).......
- **Special Aero-Engine Course**: Three weeks $35
- **Wireless Course**: Two weeks $25

**Day and Night Classes Begin Every Monday**

Write for our Illustrated Booklet “H—A Message to You on Aviation.”

### HOTEL MARTINIQUE

**BROADWAY, 332 STREET, NEW YORK**

One Block from Pennsylvania Station.

Equally Convenient for Amusements, Shopping or Business

- **157 Pleasant Rooms**, with Private Bath, $2.50 PER DAY.
- **257 Excellent Rooms**, with Private Bath, facing street, southern exposure, $3.00 PER DAY.

Also Attractive Rooms from $1.50. The Restaurant Prices Are Most Moderate.

### Monuments—Mausoleums—Statuary

No matter what your needs, we can serve you most advantageously. Estimates and designs submitted. Mail orders as carefully executed as though you had called in person. Write for particulars.

J. L. Wegenaar Co., 299 B'way, N. Y.

**SPECIALISTS IN DESIGN AND CONSTRUCTION**

### HOW TO MAKE A SEVEN-INCH REFLECTING TELESCOPE.

(Continued from page 553)

There are numerous formulae for sil-\vering the concave surface. The so-called sugar-loaf method has been satisfac-\tory used by the writer at all times. Solution (A) Silver Nitrate crystals 100 grs.; Water (distilled) 4 oz. (B) Set aside one-tenth of “A” for future use. (C) Caustic Stick Potash (pure, by alcohol) 100 grs.; dis-\tilled water 4 oz. (D) Aqua Ammonia strong. (E) Reducing Solution: Loaf su-\gar 40 grs.; nitric acid, 39 grs.; alcohol.

Pour the mixture into an enamel dish of distilled water. Drop (D) ammonia into (A) Silver Nitrate until the solution darkens and clears. Add (C) the caustic potash and drop in enough ammonia again to clear. Then add enough of the solution (B) to change the froth color without becoming muddy. Add then 8 drs. of the reducing solution (E) and pour the mixture into a porcelain or enamel dish large enough to accommod-\ate the mirror and to allow the fluid to extend about one-half an inch over the concave surface. Agitate gently and note the change of color in the fluid. When it be-\"comes a muddy pink pour off quickly and wash the silvered film of the spec-\ulum in running water. When dry the film can be dipt into fine dry rouge. The polished surface will reflect about 90 per cent of the light used. When mounted the diagram will serve both as an astronomic-\al and a terrestrial telescope. The flat mir-\ror necessary to bring the cone of light into the eyepiece tube can be a piece of se-\lected plate one-quarter of an inch thick. It can be silvered at the same time with the concave mirror.

It may be interesting to know about how much time will be required for the grinding, polishing and figuring the spec-\ulum. Of course this will vary with the particular kind of glass and the degree of one's energy, but the processes should require approximately the following: 5 hours for the rough grinding, 10 hours for the fine grinding, and 35 hours for the polishing and figuring. During the latter stage of figuring the work becomes tedious, because only a few moments of polishing can be done before the speculum is tested.

The mounting can be that of an alt-\azimuth as shown in the photograph, or a sim-\ple equatorial as shown in the diagram. The eyepiece can be of one-inch or one-half inch and one-quarter inch equivalent focus and are cheaper purchased than to attempt to make them. The ordinary microscope eyepiece (Huyghenian or negative) is rec-\ommended.

Having used both the altazimuth and the equatorial form of mounting, the writer can recommend the latter as the simpler to construct and the more generally service-\able. As the tube can be pointed at the celestial object and then clamped on and the motion around the polar axis need be con-\sidered in following the diurnal movement of the planet or the stars.

From a plank one-inch thick cut two cir-\cular discs, eight inches in diameter and seven inches respectively. Center them and screw them together with four screws. The mirror will be held flat with its back sup-\ported by a circular piece of Brussels car-

ELECTRICAL DRAFTING

Learn at Home!

The United States Government and employers everywhere are looking for skilled draftsmen. They are offering splendid salaries, and still good positions are always open because thousands of draftsmen have gone into the service. Others must take their places and carry on their work. If you are too young or too old to go to the front, learn drafting, and get into the places of men who can go and at the same time make a real start toward success in life.

No line offers greater opportunity for advancement. Drafting itself not only commands good pay, but it is the first step toward success in Mechanical or Structural Engineering or Architecture.

There is an easy delightful way in which you can "earn while you learn" with the aid of this book. In two years, International Correspondence Schools have been training men and women to be first-class draftsmen. Just the training they need for success in Drafting and more than 200 other subjects. Thousands of thousands have jumped into good positions—through I. C. S. help but never were opportunities... great as now.

Let the I. C. S, help you. Choose the work you like best in the section below, then mark and mail this coupon today.

This coupon is the first step in the right direction. Don't let it slip by. Mark and mail this coupon now.

WIRELESS

For the Men in the Draft

The Y. M. C. A. Radio School fits you in a rapid and simple way to become a wireless operator in Army, Navy or Aviation. Several hundred men and women trained in radio are needed to fill responsible commissions. The pay is good and the promotion rapid. We have trained untold numbers of young men and women who are making good salaries in interesting, rapidly developing equipment—competent instructors.

when the amount of your bill will be had. For example, if six 40-watt lamps (carbon or tungsten) burn 60 hours per month, then: $60 \times 6 = 40 = 14,400$ watt-hours, or divided by 1,000, $14.4$ K.W.H. At 10 cents per K.W.H. the bill would be $14.4 \times 10 = $1.44.

RADIO AROUND THE WORLD.

(Continued from page 547)

that trans-Atlantic communication has been successfully carried on for some time with
any such kind of the aerial being placed in the ground. Details of the exact arrangement of such ground antenna cannot be given, of course, at the present time, but the fact can be found that messages from England and other countries have been and are regularly received on this form of aerial, and also some of the high towers erected some years ago have been taken down. Another interesting point connected with long distance radio transmission and reception is the fact that an American radio engineer succeeded in picking up messages from England and other European stations in a laboratory situated on the southeast coast of the United States without any elevated aerial wires, ground antenna or anything excepting a coil of wire placed in the laboratory, the coil measuring about eight feet long and eight feet in diameter. This coil comprised about five thousand feet of insulated bell wire; by tilting the coil in various directions, by sitting at the interesting and valuable scientific measurements were taken. As might be suspected, the tuning was not quite as sharp as with this arrangement as when elongated rectangular ones were used, but the very fact that messages were received by such a small coil inside a laboratory, in comparison to the gigantic antenna erected for the purpose, is in every case a few years ago, speaks for itself.

Some very interesting work has been done in the direction of high speed wireless transmission and reception. Up to a few hundreds words per minute have been experimented with, and up to one hundred words per minute, the radio messages have been transmitted and received very successfully, fully, the received signals being amplified by means of two-stage vacuum valve amplifiers, and recorded on a meter representing the record of the cylindrical wax record type. In connection with the experiments with the ground aerials, it can be stated that no appreciable success has had the great aeronauts for transmitting with such aerials, it having been found in this case that in order to radiate the energy without too much loss, that an elevation of at least one hundred feet above the ground is usually desirable and necessary.

Long distance wireless has developed tremendously since the outbreak of the war. The great German station at Nauen, which at the outbreak of the war, included a single tower 300 feet high, has an array of towers, ranging in height from 360 to 890 feet and messages have been transmitted 3,200 miles. It is from these towers that South America has received messages in the past.

Japan is fast developing communication with the United States and altho Japanese high power stations located with Hawaii, it is planned to build stations in Japan and on the Pacific coast, a distance of over 4,000 miles, that will of commercial use.

The development of wireless between Scandinavia and the United States is making rapid strides. In Stavanger, Norway, has communicated with the Marconi station at Belmar, N. J., with good results.

Japan is to have one of the greatest wireless stations in the world. It will be built in Fukushima prefecture, says the Department of Communications, and will cost 800,-000 yen (430,000). The station will be at Hibiya, near Haraizumi, and the receiving station will be at Hosoya-cho.

Survey work has been started by engineers of the department.

EXPERIMENTAL PHYSICS.

(Continued from page 544)

stand S so that the blackened surface gets the direct rays of the sun. With this crude apparatus we are in a positive measure of the amount of energy received from the sun on each square inch in a certain definite period of time, such as second, minute, or hour. The second and the minute are almost perfect absorption qualities it possesses, and consequently its poor radiating or reflecting qualities. The heat striking the black surface is absorbed, and then conducted by the metal can to the water. The weight of the water multiplied by its change in temperature gives the heat absorbed (in calories, if weight is measured in grams and temperature in degrees Centigrade). Dividing this result by the time elapsed from the initial and final readings of the thermometer, gives us the heat received per unit of time. Dividing this result by the area of the heat units received per second, on each square inch surface. By careful determination and necessary corrections according to Newton’s law, stated in Experiment No. 99, we find that each square inch of surface on the earth receives about 10 calories of heat per minute from the sun.

EDITORIAL ASSISTANT WANTED!!!

For Popular Scientific Magazines

Young men, graduated, familiar with electrical and wireless matters. Careful and accurate in all work. Must be prepared to work under the supervision of the permanent editor, and be of good habits. Excellent opportunity for the proper man. Applicants should be ready to produce evidence of intelligence, including letters of recommendation, and a statement of salary expected, draft plan and nationality. Address—Box 9, in care of the “Electrical Experimenter,” 233 Fulton St., New York City, N. Y.

You benefit by mentioning the “Electrical Experimenter” when writing to advertisers.
while in the path of the vertical rays. From this may be calculated the total heat energy received from the sun by the whole earth. This is calculated to be equivalent to about 350,000,000,000,000 horse-power or about 250,000 horsepower for each inhabitant.

Experiment 102.

If we continue our observations (by the aid of proper instruments) of waves still longer than the heat waves we come to the electrical waves, the short,—of which are about 1/2 of an inch, running over a wide range of lengths. Waves of hundreds and even thousands of feet in length.

The following analogy between sound and electricity will serve to strengthen the wave nature of electricity. With the so-called loud pedal of the piano on, strike middle C. Placing a finger gently on the string middle C (the front panel of the piano being removed) the vibrations are felt. Since middle C is the only note that has been struck one would expect that only that string would be vibrating. Placing the finger gently on C, above or below middle C, we find those strings also vibrating. The explanation is simple: The string middle C on being struck begins to vibrate at a certain rate, setting up waves of a certain frequency the sound of which we interpret as middle C. These waves on striking the other C’s of the piano,—since the rate of vibration is similar to middle C, in fact a multiple of middle C’s rate,—start them vibrating neither faintly but sufficiently to be felt.

Let the inner and outer coats of a Leyden jar be connected to a loop of heavy wire composed of two segments D and E and a movable cross-piece F, so that the length of the loop can be altered to suit. Let jar B be connected with a loop C of fixed length. A space of about 1/2 of an inch should exist between the loops and the knobs of each of the jars respectively. On charging and discharging the jar B, a spark will jump from the knob of jar A to the loop of jar A provided the loop of jar A is adjusted so as to have the same area as the loop of jar B. On moving wire F to any other position, no spark is observed at jar A. This electrical case is similar to the sound example given above. When the electrical system of A and B is such that they have the same vibration rate, just as the C’s of the piano having the same vibration rate, then vibrations of the one cause the second to vibrate. We therefore conclude that electrical discharges are vibratory. Moving the sliding wire F is called tuning, and when the two systems are tuned they are said to be in resonance. Just as heat can be transmitted by radiation, so electrical energy can be transmitted. Electricity differing from light only insofar as its waves have a tremendously greater length and the speed of transmission being independent of the wave length. We should notice that the speed of electrical transmission equals that of light or 186,000 miles per second.

Electro-Magnetic Theory.

An intensive study of electrical radiations shows us that they not only have the speed of light but that they are reflected and refracted, etc., just as light is. Hence in modern Physics, light is considered an electro-magnetic radiation. Light waves are considered to be generated by the vibrations of electrically charged parts of the atoms. James Clerk Maxwell, as far back as 1862, showed that it ought to be possible to create waves in the ether by the use of electrical disturbances. Hertz’s experiments in 1887 confirmed Maxwell’s theory; these two events and dates really marking the beginning of Radio telegraphy. (To be continued)

Electrical Testing Engineers Made to Order.

(Continued from page 538)

tested supply most of the electricity required for testing them, only the losses being supplied from the power station.

The test men operate the machinery being tested on the machine used for testing the apparatus which has been manufactured for shipment.

With this operating experience, the graduate of the "Test course" can manage almost any main station, sub-station or switch house and take charge of its electrical operation.

This feature was probably one of the main reasons of the test men were all appointed for officers in the Army and Navy.

The fact is not as generally understood as it should be, that the students engineers are continually shifted from one kind of work to another, and are consulted regarding the sort of work they desire to specialize in and also class of testing they desire to take up month after month.

For example, if a student engineer has experience in a turbine work, he can spend 50 per cent or more of his time testing large and small turbo-generator sets. Turbines are tested non-condensing and also with water washed. For, student becomes familiar with the properties of steam, ranging from 200° super-heat down to 20 per cent moisture. One of the students is a student engineer who enters the Test Course, is the vast amount of information which he secures in rapidity.

An indication of the scale on which this mechanical electrical phase of the Company's testing has been developed, is shown by the fact that one of the test equipment was installed at an expense of $300,000 and a steam equipment is being installed at $250,000—both solely for "testing purposes." Such is practical turbine testing today on a great scale.

In comparison with this work the little jet and barometric condensers in the old power plants, 15 years ago, were but cunning little toys.

This wide variety of apparatus for steam and vacuum condensers, motors, both mill, mine and crane, motor generator sets, etc., illustrates the breadth and scope of this heavy work. It contains the latest, and hence the most interesting electrical mechanical devices that are manufactured. When the Engineer of the General Testing Lab. electrical locomotive throws his controller handle one notch ahead, he duplicates what an electrical test man has previously done. When an operator of the great electric locks of the Panama Canal throws the switches which permit a $3,000 ton battleship to pass through the also, tremendously what the student engineer has previously tested and adjusted.

The theoretical phase of the training of a student engineer is taken care of by an extensive series of lectures, which are given to the students by prominent designing, research and production engineers, and working with the commercial managers of the Company.

Not only are these lectures free but the students are paid full time while attending them. Attendance is not compulsory and a student may attend one or two each week as desired. These lectures are given between the 4th and 35th of the month, P. M.—after the close of the working day.

The purpose of these lectures is to round out the student's knowledge of the Company's products, and it is very popular. The young men are encouraged in their desire to become specialists, but are given freedom to choose the field of knowledge that are opened up to them by these various lectures. Altogether there are 50 lectures given every year.

After six months or more have elapsed since the student entered the "Test Course," he has the opportunity to choose which of those who have made a good record. The Superintendent of the Testing Department selects three men for the various offices in the Engineering and Commercial Departments, at the end of which training they then return to the Testing Department.

Popular Astronomy.

(Continued from page 543)

and more asymmetrical in appearance. They are sometimes referred to as the equatorial regions of the sun while above the poles the rays are extremely short with pronounced dark rifts between them. The equatorial region sometimes extends to eight or nine million miles from the sun. This type of corona is called the sun-spot polar. The sun-spot activity was just past the maximum for this sun spot cycle which had been reached the year before. The decline toward minimum activity was also very gradual. 

Important of the solar declination of activity, that is, a sun-tropic type corona roughly triangular in shape. The evenly developed portions toward the edge of the sun spot maximum type forming the base of the triangle and the long equatorial streamers to the east of the sun spot minimum type forming the triangle. Their greatest extent was three solar diameters or two and one-half million miles. The corona was also a petal-formed corona, most beautiful type observed in certain eclipses of the past. The rays curved and interlaced to form enormous petals and Gothic arches, and the brilliant blood-red prominences of inconstant gases that were plainly visible to the naked eye and formed a most impressive and vivid spectacle. The prominence, the arching of the coronal streamers above the prominences, to a height of several thousand thousand miles from the surface of the sun in the typical corona, that causes the eruptive prominences is accountable for the arched coronal rays above them. The prominences, which are chiefly incandescent and bright and the helium and calcium often rise to heights of one hundred thousand miles or more and then rapidly fade away. The accompanying photograph taken at Green River, Wyoming, by the Yeke's eclipse expedition, shows a number of conspicuous prominences on June 8th, and also the inner corona. Unfortunately it is never possible to reproduce in prints the complex coronal rays, tho the negatives show a wealth of detail and detail is derived from the original negatives are necessary to show this complex structure.

Since it is possible to observe the prominences on any clear day with the spectrophotograph they possess little scientific interest during totality, tho they are a most impressive and beautiful feature of the eclipse, owing to the great height they attain and their conspicuous scarlet hue and variety of form. The chromosphere, the richly colored lover rays, tinged with pink and orange colored vapors of many elements, that appears as a narrow rim above the eclipsed solar surface is also extremely beautiful and indeed the celestial color.
Boys 16 to 18 years old
Come! Join this school now

The great demand now for electrical men of trained ability, the greater demand after the war—your unlimited opportunities and possibilities in the wide field of electricity—should definitely decide you to commence your electrical education at once. Here you can obtain that thorough, practical, electrical education, training and development you will need—and at the same time earn enough money while here to pay the greater part of your school expense. If you are really sincere about becoming an electrical man of recognized, well paid ability you will take advantage of the advantages this school affords and arrange to enroll here now.

Earn While You Learn—½ day work, ½ day school

Through our Industrial Relations Department students here are provided one-half day employment with foremost commercial and industrial concerns, including electrical companies, and attend school one-half—class room, lecture, electrical laboratory and machine test periods. And as evening classes are also conducted, students may have full day employment and attend sessions evenings. In this way you can earn your way while learning—and profit also by the valuable experience you will gain in your employment—all without interfering with your studies and progress at school.

NEW CLASSES ORGANIZE JANUARY 2, 1919

TURNING AIR INTO BREAD—NITRATES FROM THE AIR. (Continued from page 541)

Thus we see that the electrical engineers abroad have actually succeeded in transforming "air into bread" as we might say. At the present time, there is no plant such as here described in use in the United States, or in fact, in the two Americas so far as we know. It is safe to say that with the gradually changing conditions resulting from the present war, and also in view of the fact that the engineers of today are continuously striving to reduce the cost of all commodities, we of the present generation and our children will live to see gigantic electric-nitrogen power plants, such as here illustrated, sprinkled across the country. It may be of interest to some of our more technical readers to trace the steps followed in the manufacture of nitrate, etc. The schematic diagram here-illustrates the steps that are used in the disassociation of the nitrogen from the atmosphere in a procedure closely following the appended outline, viz.: After the sodium nitrate has been taken from the soil by the electric arc it is admitted into the soda absorption towers, which precipitate the soda and allow the nitrate to pass on into the acid absorption towers and simultaneously the free nitrate is conveyed by means of piping to the apparatus used for the manufacture of the nitric acid, etc. But at this stage of the operation the nitric acid is condensed in the condensation tower, according to specifications by Kestner, the renowned chemist and then run into the crystallization chamber where the mixture is crystalized. There is an outlet whereby the mother liquor is drawn off and collected in a vat especially constructed to retain the strong acid. Outlets from the filtering apparatus also lead into this container, and likewise a third outlet for the force of the liquid after the mixture has been separated from the paste by centrifugal action of the Centrifuge. The Nitrate is then carried to the Silo in powder form and stored there until it is to be placed into barrels. The second line leading from the absorption towers that are shown at the center and at the bottom of the illustration, carries the acid after it has been valenciated with an additional atom of oxygen from the ventilator, past thru an oven to eliminate the moisture, superheated in the steam boiler and chilled in the condensers. This oxygen then associates itself with the nitric acid as the first step of the manufacture of saltpeter (these apparatus are shown at the upper left hand portion of the diagram). The acidulated paste is neutralized and condensed; then it is stirred until it is evenly mixed and all the lumps are broken. The ball mill comes into action at this period and grinds the paste to a powder, after which it is run thru a sieve and conveyed by a bucket hoist to the Silo, where it is dried and stored for future consumption as the regenerator of the soil and to produce better, bigger and more wholesome crops for our consumption.

A $5,000 KW. TURBO-ALTERNATOR.

The first turbo-alternator of 60,000 kw. capacity has recently been completed in the A. E. G. (German) works, and the following description is abstracted from Elektrotechnische Zeitschrift. The output of the machine is 55,000 kw. at a speed of 1,600 revs. per min. It gives 7,000 volts, three-phase, with excitation at 220 volts. The turbines work at a super-heat of 326° C, and with cooling water at 27° C. The weight of the turbine is 250 tons, of which the turbine rotor is responsible for 49 tons; the total weight of the alternator is 225 tons and of its rotor 100 tons. The entire weight of the machine, turbine and alternator, is thus 475 tons.

This machine, together with a second one of similar size and output, designed by B. Goldenburg, will be installed in the Rheinisch-Westfälische Elektricitätswerke power station, located on the site of the coal fields at the foot of the hills near Cologne. The total installation at this station (named after the designer, the "Goldenburg-works") will consist ultimately of six turbo-alternators from 15,000 kw. each up to about 200,000 kw.
December, 1918

POPULAR ASTRONOMY. (Continued from page 590)

effect of the entire solar surround- ing during the total phase is gorgeous beyond de- scription.

The Sun's Prominences—Photographed by Yerkes Observatory. This is a particular Fine View of One of the Larger Prominences.

To astronomers the all important problem in conection with a total eclipse of the sun is—the corona, its composition, the nature and cause of its radiant energy. It con- tains an element so far unknown elsewhere and named "coronium." An important re- sult that has followed from observations of the June 8th eclipse is a line of knowledge of the wave length of the characteristic green line of this unknown element. The exist- ence of one or two additional distinct coronal elements is also suspected, inasmuch as a number of lines of unknown origin appeared in the spectrum of the corona photographed on June 8th, as well as in the coronas of several past eclipses. Determinations of the positions of these lines have also been made. Tho several of them may belong to coroniuns it is likely that some of them are lines of other un- known elements. It has also been found that the inner corona shines chiefly by its own inherent light instead of by reflected sun light. The outer corona on the other hand shines largely by reflected light from the sun. It is believed that the corona is composed partly of scattered particles of matter that reflect the rays of the sun, but electrical forces are probably the cause of its peculiar etherial radiance and magnetic lines of force may cause the complex and periodically changing form of the coronal rays and streamers. It is possible that the clue to the secret of the radiant energy of the sun may lie in the yet unsolved mystery of the solar corona. Every successful ob- servation of a total eclipse of the sun brings us nearer to the solution of this im- portant problem. By correlating a series of observations made by different eclipse ex- peditions at various total eclipses of the sun or by different observers of the same
eclipse the handicap of being granted only a few brief moments at long intervals for the solution of a perplexing problem is largely overcome.

(Watch for next Installment.)

ELECTRICAL EXPERIMENTER

Pay-Raising Books at Reduced Prices

Here's your chance to get at bargain prices—a set of books that will fit you for a better job and higher pay. Yes, and you may pay the bargain price at the rate of only $1.25 a week. But you must act now. The fixed cost of paper and binding materials won't permit us to continue this offer indefinitely. So order immediately. Examine them carefully—use them on your work for an entire week. If, at the end of that time, you feel that they aren't worth many times what we ask, send them back to us. If you keep them, pay the specially reduced price on the easy terms explained below.

Shipped for 7 Days' Examination

We'll gladly send any set of books to you for seven days' examination, shipped express at cost. Examine them carefully—use them on your work for an entire week. If, at the end of that time, you feel they aren't worth many times what we ask, send them back to us. If you keep them, pay the specially reduced price on the easy terms explained below.

A TRANS-ATLANTIC 10,000 HORSE-POWER AERIAL LINER.

(Continued from page 537)

EACH motor, or a total of twenty-four blades to the machine. The general contour will be similar to the illustration of the "Etheric." The exhaust from the engines will be used for heating "muffler" stoves, upon which all of the food in the dining car can be cooked, water will be heated, and a general warmth provided in cold weather and while flying at unusual heights.

Quite an appreciable amount of reserve lifting power is used in order to provide comfort of the passengers in the way of cushions, hammocks, and periodicals.

The "Etheric" is equipped with a wireless outfit having a range of up to two thousand miles, and each passenger is taken care of in the event of accident by an individual combination parachute and life-belt, for he should drop from the altitude over which he was flying, all of his body would be brought beyond a trace of recognition. These parachutes are stowed at the back of the operator's compartment for the benefit of each state-room, all of the room-fronts facing the exterior of the ship.

It is then a very simple matter in the event of an unforeseen emergency, for the passenger to jump out of bed, open the door, slip on the life-belt and parachute hanging behind him, and forgetting all fear, make his exit quickly. The parachute will open, and he will float gently to the surface of the water, in which element he will again take care of himself.

Use will, of course, be made of the Radio Direction Finders, which will be in a synchronous tune with New Foundland and Irish stations. Messages from radio stations of other stations will be immediately recognized, as this is due to the close tuning between the line's station and the station for which we are listening.

We had all better buy Liberty Bonds, so that by the time they will mature, we will have money laid away in order to buy a ticket for the trip through the high thousand feet in the air, across the Atlantic, and at a speed of one hundred and ten miles an hour with all the advantages of comfort.

Note—The motors necessary to propel this gigantic machine would necessarily have to be of approximately 1.9 or 2 pounds weight per brake horsepower. At present we have motors that will develop a horsepower at a weight of 2.5 pounds per brake horsepower.

It is of interest to note that at the large aviation fields maintained by the government, the airplane are called "ships."

EXPERIMENTAL MECHANICS.

(Continued from page 557)

The main point of accuracy of split-chucks lies principally in the fact that the mandrel, made especially large and held in the first set of jaws, is not only accurately fitted to ground-in bearings of glass-hard steel, but is in itself, the chuck body for the receptacle of the Fractioned sets of jaws, of which one split-chuck may be regarded as a set. To bring this about, the mandrel is bored true through to as large a diameter as possible and is further coned out at the front end to an included angle of 45 degrees. It can be clearly seen that these forms are made of such accuracy of sledge hammer blow will put the running of this internally coned surface out of truth with the lathe axis. All the principal grips of the split-chucks for the makes of one size externally, to fix exactly into the mandrel bore. They are bored exactly to the size of the hole and are intended to grip, screwed at the back end, in friction form, but what is called a split-chuck. By placing within their grip around work of the size they are intended to hold, and drawing them in tightly to the mandrel end by means of a hollow draw pin, screwed to their back end, and working thru the bore of the mandrel, absolute precision is obtained within limits where .001 (one one-thousandth) of an inch would be regarded as a serious error.

In order to procure accuracy of the finished material or product, it is essential that the means of chucking the work plays a very important part. Where precision is desired, no other than the split-face chuck should or can logically be used.

(TO BE CONTINUED)

WORK OF BELGIAN COMMISSION AMERICAN RED CROSS.

The American Red Cross, thru its Belgian Commission, has authorized the installation of an electricity storage battery plant at the colony of 400 Belgian children which it is supporting at Recques. These children are refugees from the towns in which the fighting is going on today on the Belgian front.

SPECTROSCOPIC METHODS AND SPECTRA.

(Continued from page 555)

be slit. This clip is made of sheet brass, also the copper and may be used over the arc is struck by moving this carbon forward back they both touch, and then moving them back about 1/2 to 3/4. The current connections made to the holders or clips should be connected to binding posts on the base.

A sheet of white cardboard tacked to the back will show the form and color. The current is used is the 110-volt lighting current. A rickets is used in the circuit.

Their brightness has been, full of water and adding 3/4 to 1 oz. hydrochloric acid and then immersing the strips in it. The amount of current can be varied by lowering and raising one of these strips. The wiring connections are shown in the figure.

It is advisable, if this apparatus is used for the house fuse plugs have not less than 25 amperes capacity, as the usual house fuse is 15 amperes rating, which will burn out in a short time, especially if too much acid has been used in the water.

It will not be out of place here to refer to the advantages of a number of places in the article. These are mainly connected with the fact that the means to produce the spectre sometimes give a continu- ous spectrum of all the elements completely blots out the band spectrum. This can only be overcome by using very narrow slits, but if a very narrow slit is used, the illumination must be increased. It is really advisable to make about six slits, in which they vary in size from one large one, about 1/8 diameter, and five small ones, in which the smallest should be about as wide as the thickness of a sheet of writing paper. A set of these will greatly facilitate good work.

This covers briefly all the general fields of spectroscopic work, but several miscellaneous items still remain.

The instrument is pointed at the sun, a continuous spectrum will be seen, which, however, is most by a considerable number of blinks, and it is the theory that the sun is a white hot mass of solid matter, surrounded by a mantle of gaseous vapors. These vapors are then, ordinary circular with a background of incandescent matter, they are reversed, and appear as black lines on a colored background.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
It is obvious that by comparing these lines with ordinary spectra, we can tell what elements exist in the sun. This has been done, and the sun has been found to contain chiefly iron, sodium, magnesium, calcium, chromium, nickel, barium, copper, zinc and hydrogen. Hydrogen especially has been observed in enormous quantities.

One of the iron spectrum (which contains an enormous number of lines) has also been identified. It is also a fact that the sun contains quantities of certain metals not known on earth. One substance has since been discovered, namely, Helium, and it is a startling fact to confess that this element was discovered in an incandescent body millions of miles away in space before it was known on our own little globe.

An experiment to illustrate this reversal of the spectrum can be made by placing a sodium flame in front of the spectroscope, and behind it a small arc. The yellow band will disappear, and the continuous spectrum of the arc will be cast upon a black line where the yellow should be. The experiment can also be made with other elements, but the result is in every case the same.

A little consideration should now be given to the best materials, etc., used to obtain the spectra. As a general rule, it can be said that the halogen salts, that is, the chlorides, bromides or iodides, are the best to use. The chlorides being the cheapest and most easily procurable, are generally used.

The reason these salts are the best is because of their instability at the high temperatures used. They are decomposed (dis-associated is the more correct term) into the free metal and radical. Care must be taken, however, with these salts, for example calcium chloride, which yields a spectrum of its own which lasts until it is decomposed into calcium oxide; and, in fact, if possible, it is best to use the oxide instead of the chlorid.

The foregoing remarks apply equally alike to flame, spark and arc spectra, but in the case of the light being used, in which it is evident that the temperature is not nearly so high as the arc and spark methods, materials can be used that will materially aid in producing the spectrum. The salts referred to are the chlorides, which practically amount to a chlorid with a certain oxygen attached. When, for instance, calcium chlorid is introduced into a flame, the heat begins to drive off some of the oxygen, which, in proportion to the temperature of the flame, in which the residual chlorid is being volatilized. It will, therefore, be seen that the use of the chlorides where available, for flame spectra, is a decided improvement.

The nitrates can also be used in a similar capacity, but are not so efficient as the chlorides.

It will be well to again repeat the warning that nitrates or chlorides must never under any circumstances be used for arc spectra, as the combination between them and the carbon of the electrode, making practically gunpowder, at the temperature of the arc, may result in a dangerous explosion.

It is to be hoped that enough has been said in the preceding articles to give to the careful and earnest Experimenter some small glimpse of the wonders that can be revealed with a very little expense, a normal amount of ability and patience, opening up as this subject does, such a fascinating and entertaining field of work, and yet it is a strange but true anomaly that the more we learn and the farther we extend our knowledge the stranger becomes the conviction that we know less and less of it than ever before.

(Conclusion)
Further Increases Coming!

**NOW IS YOUR CHANCE!**

With this issue, the price of the EXPERIMENTER, as announced on another page, goes to $2.00 a year. With the paper market in chaos and soaring prices, printers demanding another large wage increase, engravings going up 90%, we feel sure that before spring ALL magazines will go much higher than now.

By subscribing now for one to five years, YOU POSITIVELY WILL SAVE BIG MONEY.

The prices below are unquestionably the lowest for standard magazines that it is possible to obtain anywhere. Only by a special arrangement with the publishers are these prices possible and they are good only until December 16th, after which date all prices as given on this page are withdrawn. Make up your list at once—do not delay. If you are not already a subscriber and your subscription to the EXPERIMENTER runs no long time, you may subscribe for any other magazine by deducting the price of the EXPERIMENTER from the clubs at the rate of $1.85 (the special price allowed in clubbing with other magazines). Thus you can make up any club yourself of as many magazines as you wish from the list below.

All prices quoted are for subscribers in U. S. only. Canadian and for sign subscriptions require additional postage.

Opportunity Ai-lets

YOU will find many remarkable opportunities and real bargains in these columns. It will pay you to read and investigate the offerings made here, as many of the firms who advertise sell other than the items advertised. Here is the place where you will find the most attractive opportunities at the lowest prices.

Advertisements in these columns are accepted only as a service for the benefit of the reader. The publishers are not responsible for the truth or accuracy of the statements made in any of them. Cash must accompany all classified ad. It is advisable to have a list of the items you wish to buy before you_send money. A return of second-class postage stamps will be allowed on money paid for classified ad. It is the publisher's policy to make the best market for each item advertised. This policy cannot be changed to include or exclude any item. Cash should accompany all classified advertisements unless placed by an accredited advertising agency.

Write early to receive discount announcements and information on the lowest rates. Objectionable or misleading advertisements not accepted. Advertisements for the January issue must reach us not later than November 22.

The Circulation of the Experimenter is over 100,000 and climbing every month

For Inventors

Inventors—Mail your inventions, through National Institute of Inventors, World Bldg., New York City. Membership co-operative organization.

Thousands Government jobs open to men, women, girls, 55.00 month. Quick increase. Write immediately for free list of positions open.

Wanted—To buy American Toy Manufacturers, to make Toy Soldiers, Army, Navy and other toys. Home workers on small scale, manufacturers on large scale. Greatest chance for industry and consumers in America. Enormous demand in American Made Toys. Will buy your toys, dolls, or anything in good condition. Will pay largest prices. Complete outfit for manufacturers wanted. Write for free list of manufacturers. Many men—Who know what they want and who have the necessary capital to start huge lines. 

Patent Your Own Inventions. Save your attorney’s fees; prepare applications; furnish full information and quotations. Free information. Mr. C. L. Orton, 371 East 10th St., New York City.

Science and Industry—Patents—Without advance attorney’s fees. For full information and quotations, send 10c for free book, Books free. Frank Fuller, Washington, D. C.

Inventions Wanted! Manufacturers constantly writing us for patents. List of inventions accepted. Write for complete information. Mr. C. L. Orton, 371 East 10th St., New York City.

Complete Chemical Laboratory for sale or exchange for wireless goods. Rakosy, 331 East 80th St., New York City.

Strongest Force Courses, $100. Clay Hewes, 102 S. Lake Ave., Albany, N. Y.

Send for free booklet. $50.00 value. Speedily advancing. Contains practically unobtainable equipment. Pratts, 1050 W. Workman Ave., Los Angeles, Calif.

Wanted—Screw cutting bench lathe or high frequency apparatus. Have 20 Vol., Encyclopedia Britannica, complete leather edition, good as new. Address Nestor J. Saffoon, Buffalo, N. Y.

Electrical Laboratory For Sale—Send for list of everything in stock. Ray Wengel, 29 W. Dotty St., Madison, Wis.

Everywhere—Worth while samples 50c. Mention subjects preferred. Mutual Exchanges and New Inventions. Write to Mr. C. L. Orton, 371 East 10th St., New York City.

For Scientific Exchange Columns

LIE readers with something to "swap" or sell have found that the surest and quickest way to make the desired trade is thru ad in these columns.

The rates are:

Five cents per word (name and address to be counted.) Remittance must accompany all orders. No advertisement for less than three dollars accepted in Opportunity Ad. columns only.

OVER 100,000 CIRCULATION

Printed

100 Bond Noteads, 4 lines and 100 envelopes prepaid, $1.00. Southern, 149II Berendo, Los Angeles.

Beautiful Lithograph Stationary at Printer’s Wholesale Prices. Free Descriptive Lithograph Co., 708 E. Tenison, Milwaukee.

For Sale or Exchange—Rausch & Lemberg microscope, magnifies 24 times, Physics Laboratory equipment, florist's supplies, 36 lbs. wheatstone bridge, etc. Want Xela and spark coil, etc.

Will Exchange—New $1 #1 Meccano for Chemical Laboratory Outfit. Charles Blake, Fayette Street, Wolcott, Conn.

Sold—Small stamp collection cheap. Write, Granville Whittley, Jr., 120 E. 67th St., New York City.

EXPERIMENTERS!

A Sample of What You Can Do With This Outfit

This illustration, made from an actual photograph, shows only a very few in\\nstruments that can be performed with this wonderful outfit. The RADIONOE, a 'truly a

The "Electro" Radiophone

The "Electro" Radiophone is not a toy, but a practical, honestly built telephone outfit, which

No. EX2002

"The Boy's Electric Toys" contains enough material to make and complete over twenty-five
different electrical apparatus without any other tools, except a screw-driver furnished with the outfit. The box contains the following complete instruments and apparatus which are already assembled:

Student's chronic plunger battery, compass-galvanometer, solenoid, telephone
receiver, electric lamp. Enough various parts, wires, etc., are furnished to make the following apparatus:

- Electromagnet, electric camera, magnetic pictures, dancing spiral, electric
  hammer, galvanometer, voltmeter, hook for telephone receiver, condenser,
  sensitive microphone, short distance wireless telephone, test storage battery,
  shock coil, complete telegraph set, electric riveting machine, electric buzzer,
  dancing flames, singing telephone, mysterious dancing man, electric jumping
  jack, magnetic geometric figures, rhesus, erratic pendulum, electric butterfly,
  thermo electric motor, visual telegraph, etc.

This does not by any means exhaust the list, but a great many more apparatus can be built actually and effectively.

With the instruction book which we furnish, one hundred experiments that can be made with this outfit are listed, nearly all of which are illustrated with superb illustrations. No other materials, goods or supplies are necessary to perform any of the one hundred experiments or to make any of the 25 apparatus. Everything can be constructed and accomplished by means of this outfit, two hands, and a screw-driver.

The outfit contains 14 separate pieces of material and 24 pieces of finished articles ready to use at once.

Among the finished material the following parts are included: Chronic salts for battery, lamp socket, bottle of mercury, core wire (two different lengths), a bottle of iron filings, three spools of wire, carbons, quantity of machine screws, flexible cord, two wood bases, glass plate, paraffin paper, binding posts, screw-driver, etc. The instruction book is so clear that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the layman with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The size of all the outfit is 14 x 9 x 2 3/4. Shipping weight, 8 lbs.

No. EX2002 "The Boy's Electric Toys" outfit as described.

FIGHT or Join the Industrial Aircraft Service

You may not be free to get into the actual fighting, but you can still give valuable service to your country. Join the Industrial Aircraft Service and you’ll not only be serving where you’re most needed but you’ll be laying the foundation for your future success.

Here is both Duty and Opportunity.

Here is your chance to get into essential war work, serve your country and make a good connection in the industry that’s fast becoming one of the foremost in the world.

The Aircraft Industry is more than a wartime emergency. The Aerial Mail Service has established the definite commercial value of the Aeroplane. After the war there will be opportunities aplenty for men who make good in the Industrial Aircraft Service now.

An Opening for You in One of America’s Foremost Aircraft Plants

At present our plants in New Brunswick (N. J.) and Long Island City are engaged solely in the manufacture of Aeroplane Motors for the Government. To meet our ever increasing schedule of production we must have the man power to operate the machines in our various departments.

We want your help. We want skilled mechanics, machine operators, inspectors, draftsmen, etc.

We will pay good wages for the right men.

Our Offer to Men Not Technically Trained

You do not have to be a skilled mechanic to get started with us.

If you have the right spirit and the determination to learn, we will take you on and train you at our expense in our School of Instruction.

Not only will we give you, free of charge, a full course of practical instruction under the supervision of competent instructors, but we will pay you while you are learning.

When you have completed the course which takes about ten days, we will pay you full wages prevailing in the factory.

Living Conditions Good

Living conditions in New Brunswick and vicinity are being bettered every day. Every Wright-Martin man will be able to count on a comfortable and congenial place to live. Moreover, the Government is now building 200 houses especially for war workers at Wright-Martin and other factories.

The company provides for social and recreational activities for everyone. With baseball, football and track athletics, picnics, concerts and dances, there need be no dull times for you or your family in New Brunswick.

One Hour from New York City

New Brunswick is just about one hour out of New York on the Pennsylvania. It is within short commuting distance of Newark, Elizabeth, Trenton and Philadelphia.

Your Duty Is Here

In fairness to yourself you can’t afford to pass up this opportunity to advance yourself and serve your country, too.

Write, phone or apply in person to Employment and Welfare Department, Wright-Martin Aircraft Corporation, New Brunswick, N. J., and Long Island City, Starr and Borden Avenues.

Price 50c.

**Cigarette Roller**

Very neat and handy. Works less than a quarter of an ounce. I make a roll cigarette and you can buy as many as you wish. You save money and get a better cigarette. Price 10c each.

**Latest Novelty: Aerial Balloon**

Flies easily and smoothly. With a little practice you can make your own. Price 10c each.
A Grand, New Opportunity for Young Men in America

Thousands of Wireless Operators Wanted—at Big Salaries

A few short years ago wireless telegraphy was only the dream of dreamers. Today it is one of the most important of modern industries. Its usages are widening with terrific rapidity, until it is now considered an essential to the progress of man. So great has been the growth of wireless that there are now over 30,000 unfilled openings for Radio Operators.

Master Wireless in Ten Weeks

The National Radio Institute, headed by authorities who are now closely allied with governmental training of students, has perfected an easily mastered course in wireless telegraphy whereby students are taught completely in ten weeks. Many of our students are ready to take up actual wireless work in much less time. The course is founded on actual practice, hence the rapidity of the progress of the student.

THE PRICE IS REASONABLE—EASY TERMS

Our unusual facilities enable us to teach thousands of students by mail, affording them the same efficient service as if they attended our big school here in Washington. Herein lies our ability to offer this course at a figure which everyone can afford. To those unable to pay the full amount on entering, we offer easy terms of payment.

America Takes Her Place on the Seas

America is spending billions of dollars on the mightiest navy and merchant marine in the world. Practically all vessels are being equipped with wireless apparatus of the most up to date type. Thousands of operators are needed now. Salaries are high, and constantly rising. The field affords a wonderful opportunity for the man who starts now to master wireless. He can enter the navy, the army, the aviation field, the merchant marine, or a land station. Operators are needed badly in all of these branches of governmental and private industries.

Be a Trained Man in 10 Weeks

In the short period of ten weeks we can make of you a wireless operator, a man with a profession, independent, and not subject to the rise and fall of wages in the labor market. Salaries are as high as $150 per month and expenses. The man who acts now is the lucky one. Such glowing opportunities do not present themselves often in a life time.

These are the instruments you work with—they are given FREE with your course.

FREE BE A CERTIFICATED ELECTRICIAN

YOU MEN LISTEN

The country needs more trained, graduate electricians. Thousands have gone into the Government service and there is such an unusual demand for competent electrical men that I am making a wonderful offer at this time. HERE IS YOUR OPPORTUNITY! I want to send you my splendid offer now.

Don't hesitate because of age or experience. Young men, boys and old men must now fill the gaps and keep business going. DO YOUR PART. Prepare yourself for a real position, by my Home Study Course in Practical Electricity. I am Chief Engineer of the Chicago Engineering Works. I have trained thousands of men and can help you better than anybody else. We also have large, splendidly-equipped shops where you can come at any time for special instruction without charge. No other correspondence school can give you this.

SPECIAL OFFER: Right now I am giving a big, valuable surprise that I cannot explain here, to every student who answers this ad. Write today!

$46.00 to $100.00 a Week

Go after some real money. Qualify for one of the thousands of splendid positions open. All you need to start is a few months snappy, practical instruction from a competent engineer. Come to me—NOW. I'll give you my personal care to ensure rapid and efficient progress. My course is intensely practical. It is highly condensed, simplified, up-to-date and complete. I am so sure you will make a splendid success in this study, that I will Guarantee Under Bond to return to you every cent paid for tuition, if you are not entirely satisfied when you receive your Electrician's Certificate granted you as a graduate of my school.

FREE—Lessons and Outfit—FREE

Send me the Free Outfit Coupon at once. Do it now! For a limited period I am making a slashing cut in the cost of tuition, and giving each new student a grand outfit of Electrical Tools, Material and Instruments—in addition—Absolutely Free. I will also send you—free and fully prepaid—Proof Lessons to show you how easily you can be trained at home to enter this great profession, by means of my new, revised and original system of mail instruction.

ACT PROMPTLY

Get the full benefit of this great offer. Send the Coupon or a postal for free information without delay. Do it now—before my free offers and guarantee are withdrawn.

A letter that means something to every man in America who is interested in electricity

McGraw-Hill Book Company, Inc.,
239 West 39th Street, New York, N.Y.

Gentlemen: In an attempt to express myself about CROFT'S NEW LIBRARY OF PRACTICAL ELECTRICITY, I have never seen and do not believe there was ever printed in the English language, a more comprehensive set of books. It is a library that is just as valuable to the novice as to the expert, because it is all practice.

Respectfully,
GUY H. PEIFER,
Chief, Duplan Silk Corporation, Hazleton, Pa.

McGraw-Hill Book Co., Inc.
239 West 39th Street, New York, N.Y.
Here are many different ways of producing music, and as our culture advances the desire for better and still better music becomes a craving of civilization. From the ancient tom-tom to a Stradivarius violin is a long story, and the changes are that as our musical tastes become more refined, still better instruments will become necessary and highly desirable.

There are few instruments giving a more mellow and a more “human” sound and quality of tone than a fine violin, but we have no hesitancy in saying that it should be possible to obtain still better results by electrical means. The field of purely electrical music has hardly been touched. Some years ago an American inventor produced the Telharmonium. This was one of the earliest and best attempts at pure electrical music. The Telharmonium was invented by Dr. Thaddeus Cahill and he used alternating current generators, each of a certain frequency; if a telephone receiver were connected in the circuit, the latter would give forth a certain very pure note. By using a switchboard arranged in the form of an organ keyboard, wonderful musical effects were produced.

Another more recent attempt was the pure electrical music discovered thru researches of Dr. Lee de Forest. He used his audion bulbs in connection with a telephone receiver, and obtained beautiful flute-like tones of the greatest purity. The two devices just described necessitated the use of a telephone receiver to translate the electrical impulses into sonorous vibrations, and this is a great disadvantage, for it ties us to a thin diaphragm, which in itself cannot produce the very purest tones obtainable. As one can readily understand, the limitations of a diaphragm are very great and while it is possible to obtain a single pure note, it is a different matter where several pure notes in different octaves are to be reproduced simultaneously.

A way out is suggested by the writer by pressing into service the thermo-telephone which employs no diaphragm at all, but uses a very fine platinum wire of microscopic cross-section. This platinum wire, heating and cooling in unison with the electrical vibrations, impress upon it imparts these impulses to the surrounding air. With this device very pure electrical music can be obtained.

There should be of course many other ways to actually produce pure electrical music, and here is a wonderful opportunity for experimenters and inventors. To the writer’s mind, it seems not at all impossible that we should take a metallic wire stretched taut and by impressing the electrical current upon it, vary its heating and cooling effects so as to produce pure sounds in a suitable receiver such as a thermo-telephone.

Dr. de Forest has shown us that beautiful music can be produced in a vacuum tube. Paradoxical as it seems, this nevertheless is a fact. There must be many other ways of producing vibrations in a vacuum tube which can be translated into an electrical current, thus producing music.

There are also certain ways of making electromagnets produce music—this without the adjunct of telephone receivers,—by vibrating their entire structure. Many other means will undoubtedly suggest themselves to our students and scientists.

H. GERNSBACH.
Wireless in Ten Weeks

(We teach you in your own home during your spare time)

Thousands of operators needed for
America's Merchant Marine

The age of wireless is here. The experimental stage has passed. Wireless now equals in importance telegraphy, and telephony. It has assumed its place among the great commercial industries of the earth. So rapid has been the development and growth of wireless in recent years that there has been left in its wake a tremendous shortage of operators. Actually thousands upon thousands are now needed for permanent "peace time" positions offering wonderful opportunities for advancement.

Earn up to $200 per month

In the short period of ten weeks we can make of you a wireless operator, a man with a profession, independent, and not subject to the rise and fall of wages in the labor market. Salaries are as high as $200 per month. There is a position in the merchant marine, the army, the navy, or a land station, awaiting everyone completing our course. We give you this training at home, by mail, in your spare time. It is not necessary for you to lose any time from your work to take the course.

Free Instruments—

To every student enrolling with us we present a standard set of instruments with which wireless messages may be sent and received.

Travel the world over or locate at a land station in America.

America is spending billions of dollars on the mightiest navy and merchant marine in the world. Practically all vessels are being equipped with wireless apparatus of the most up to date type. Thousands of operators are needed now. The field affords a wonderful opportunity for the man who starts now to master wireless.

Our students actually pass the commercial examination in ten weeks or less.

Get your instruction from the Nation's Capitol. Our course is endorsed by officials of the U. S. Government.

Master Electricity By Actual Practice

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

The Oldest and Only Institution of the Kind in America

At this “Learn by Doing” School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

Over 5,000 Students now holding Successful Positions in the Electrical World

5,000 of our students are today successful electricians.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions.

Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

American Destroyers Throw "Depth Bomb Barrage"

A n American destroyer, with her depth bombs ready to be discharged, is a dangerous craft. Running without lights in the darkness she is a menace not only to the enemy but to herself and other ships should a collision occur.

The bombs are now released from every quarter of the destroyer. Two can be dropped from the bridge by pressure of a button; "Y" guns, amidships, with two barrels, can throw bombs to port or starboard; astern there are two long lines of bombs running on miniature railway tracks, so a complete barrage may be fired at any point where the subaqueous explosion occurs.

The detail view herewith of one of these depth bombs shows clearly the principle upon which they operate. The steel tank container is a simple affair, fitted with a sensitive water-pressure diafram. The pressure of the water increases .433 lb. per square inch for every foot of head or depth. Thus for 1 foot depth the hydrostatic pressure acting on the shell, and also the diafram, would be .433 lb. for every sq. in. of surface area. For a depth of 20 ft. the water-pressure per sq. in. would be 8.6 lb.; for 50 ft. depth, 21.6 lb., and for 100 ft. depth, 43.3 lb. per sq. in. Hence it is clear how it becomes possible to "set" the diafram of the detonating device, whether electrical or mechanical, to trip off the latter at any desired depth. The farther the contact pin, or trip finger, is set back or away from the diafram, the greater the water-pressure or depth required to press it in that far.
ELECTRICAL EXPERIMENTER

January, 1919

AND NOW THE ELECTRICIANNETTE!

We have conductedettes, female bartenders, police women, elevator operators, usherettes and farmerettes, but this is the first instance, so far as I know, of where we are having an electricianette.

Mrs. Ada B. Vail of the Atlantic City Electric Company, Atlantic City, New Jersey, has complete charge of an installation of sixty-five electric ranges in one apartment house, located at the above address. She is responsible for the proper maintenance and operation of the entire equipment of these stoves and handles her position capably. Beside, she takes care of some thirty-five odd city stoves, at the addresses where they are located. She supervises one hundred of these in the various electrical devices.

Her entire tool kit can be summed up in a testing lamp, screwdriver and two pairs of pliers, one large and one small. Compare this neat and compact equipment with most certainly reflects the characteristics of a woman as its owner, with the modest (?) tool chest of the male species of electrician and the carrying of a large assortment of unnecessary junk, approximating one-half ton in weight, and when he finds that the job will require a screwdriver one-sixteenth of an inch smaller in size! We would be asking too much if we should expect him to use one of the next size. Instead he takes an afternoon's vacation on your time, going to the nearest place to Coney Island, or Kalamazoo, as far as we know, and by the length of time that he consumes to get this tool.

Can you imagine upon arising from your warm bed on a cold Winter morning, making a quick dash to the electric stove in the sitting room, turning on the switch, and in anticipation of the warmth that you are to get, you find the electric stove is as cold as a chunk of ice. The heat of your indignations warms you thoroughly, and you make a great dive for the telephone. After you have stood there for about a half hour with your teeth chattering, waiting for the telephone boy in the hall below to answer your call, you are finally rewarded for your patience by being allowed the honor to speak with the janitor. After you have told him what you thought of him and his entire family, back to his great, great, great grandfather, he very sweetly answers with a roar like the Kaiser and tells you that your need will be attended to.

Within a few seconds you hear a short staccato knock upon the door, and upon opening it you are almost stricken speechless by the appearance of a very neat and chiselled young lady, in overalls. Taken back with this surprise, you ask her what she desires. "Oh, Sir," she says, "I am the electrician! You sent a call for me, and I am here to repair your heater."

The interior of the room is not very agreeable to you, and with military precision she brushes past you, takes off the top of the heater, yanks out the heating elements, moves a most inflammable, that sounds like "burnt out," inserts a new one, attaches another fuse, turns the switch, and the job is finished. It has taken her exactly ten minutes, and the most incredible part of it, is when you ask her the charges, and receive a reply, "Oh, that is received, sir. I am paid by the firm that owns the building. She goes out closing the door very gently, and without even looking for a tip.

Cheer up, fellows, it will be a great old world after the fair sex take our jobs. We will have nothing to worry about except washing the dishes and scrubbing the floor.

WORLD RADIO SYSTEM URGED FOR SOCIALISTS.

Active steps are being taken by the International Socialist movement to establish a private system of wireless throughout the world. Five installations are already indefinitely projected. Stations will be immediately set up in England, France, Belgium and ultimately in other countries, including America.

Three of the new stations will be linked up with the German and possibly the Russian Socialist wireless. They will be used to connect Socialist organs in various countries.

In collision there is no danger of the shock exploding the bomb, but some might be thrown into the water and explode when at the proper depth.

And this is not all of the Depth Bomb's story, either. Did you ever hear of the depth bomb gun? It shoots depth bombs accurately for a distance of half a mile or more. The merchant ships that dodged the U-boats were equiped with such guns, which operated with almost perfect air, similar to the well-known torpedo tube. The illustration shows how the depth bomb gun is sighted to drop the bomb just at the point where it will make a complete trajectory thru the water and explode near the enemy submarine, which has submerged and is sneaking off, or trying to.

In this also, the effect of a subaqueous barrage on the enemy subsea fighters. Talk about land barrage fire! The water transmits the noise and vibrations from the exploding depth bomb many times better than in the air. Cases have been known where a submarine's plates have been dented in and the seams started at a distance of nearly one-half mile. The concussive wave transmitted thru the water is exceedingly powerful, because, for one reason, water is practically incompressible.

Remembering that stores of munitions in the German naval ports first gave clear intimations that Germany's military machine was breaking down, it is not surprising that the revolutionary movement first should have assumed serious form among the sailors. And according to the current reports, the terrible hardships and the ghastly number of fatalities among the U-boat crews were what started the final fatal break in discipline and morale.

It can be said, therefore, with some approximation to truth, that not only did unrestricted undersea warfare hasten and make certain the defeat of Germany by bringing into the war the American land and water forces needed to turn the scale against her, but it was the thing which, working from the other side of our speed to the downfall of the Kaiser's hopes and his empire. The fears and the despair which the submarines could not create in the minds of the Allies did create in those of the men who had been ordered to commit the atrocious crimes by which the world was shocked.

They did what they were told to do, but the task proved too much for even their docility, and they rebelled against it at last, not, however, so far as any evidence yet presented has shown, because of indignation against the order, but because the execution of those orders so often meant for them the fate of drowning rats. Too many of the U-boats that went out did not return, and the mystery of their fate was intolerable to the survivors.

BACK NUMBERS.—Many readers desire to obtain back numbers of this Journal. We have a limited quantity of these back issues on hand and can supply them at the following rates—Back Numbers of The Electrical Experimenter not over three months old, 15 cents each; over three months old, 20 cents each; over one year old, 35 cents each.
Solar Engine Uses Sun's Energy

Six thousand degrees Centigrade is the computed temperature of the sun. Its light giving power is equal to 27,000,000,000,000 candlepower, a quarter of a mile away. Scientists tell us that only the 2,735-millionth part of the total energy radiated from the sun reaches our earth, but this was ever ceased to stop for any reason our planet would turn into a dead, rigid ball of rock; the present average annual temperature of 13° C., would change, without the heat of the sun, to 73° C., of frost, it is calculated.

Experiments show that the power of the atmosphere to trap heat is largely due to the water vapor that it contains. It is also due to some extent, to the carbon dioxide gas that is one of its minor constituents, points out Prof. Garrett P. Serviss. Carbon dioxide is a remarkable heat retainer, but there is only a very small quantity of it in the air compared with the vast bulk of the atmosphere. It only amounts to about 3/100 of 1 per cent. But there is this significant fact about it, viz., that its amount is variable, to a slight degree at the present time, while there is evidence from past geological history that once it was vastly more abundant than it is now.

Now, how much carbon dioxide must the air contain in order that a perceptible effect on the temperature may be produced? Arrhenius answers this question for us. He says that if all the carbon dioxide now in the air were removed, the average temperature would fall nearly 38 degrees Fahrenheit. On the other hand, if the present amount were doubled, the temperature would rise more than 7 degrees, and if it were quadrupled, the rise would amount to nearly 14 1/2 degrees which would be far more than enough to banish all the glacial suffering that we had to endure last winter. Even the smaller amount of increase (7 degrees) would probably suffice for that.

These facts are very interesting from a technical point of view, indeed. The practical aspect of solar energy lies at present in the hands of those who are endeavoring to perfect a solar motor—i.e., an engine or electric generating device which, when the sun's rays strike it, will develop steam to operate a steam engine, or electricity to charge electric accumulators or storage batteries. Those interested in this branch of science will find of great interest several articles which have appeared in back numbers of this journal.

Considering later developments of a practical nature in the line of solar engines and boilers, we may take up the work of Mr. Shuman, of Philadelphia, Pa., who later collaborated with a Mr. Boys, of England. They were able in their final developments to operate a 100 horsepower engine by means of solar energy. This plant was built at Meadi on the Nile, Egypt. Prior to this excellent work, however, we may consider briefly the early solar engines developed and tried out at Philadelphia, Pa., by Frank Shuman, upon which work he started in 1906. One of these solar engine plants installed in

Voltaic Electric Plant in Italy Develops 15,000 H.P., March, 1917, Issue: page 789.

Texas being illustrated herewith. The heat of the sun's rays strikes a large number of mirrors, which reflect the heat to special boilers. These produce steam to run an engine, the latter operating an electric dynamo. The current thus produced was capable of operating an electric motor pump which pumped water to a height of 60 feet above the ground.

Mr. Shuman had running at Tacoma, Pa., a practical plant of this type, which developed about 3 1/2 horsepower by using 1,200 square feet of sunshine that was allowed to fall on a 30 horizontal water box. This box was fitted with a glass top and a series of parallel horizontal black pipes were immersed in the water. These pipes, containing either exposed 900 square feet of surface to the solar radiation. The water also became heated and carried the heat to the underside of the pipes, thus realizing a greater efficiency. The ether boiled and its "steam" drove a small vertical, single cylinder engine. The exhaust ether vapor past into an air surface condenser and the liquid ether from this was pumped back into the tubes of the sun boiler. It was found that this plant worked well even with snow on the ground, which is explainable from the fact that the permeability of the atmosphere is about 20 per cent. greater in winter than in summer.

Further tests and refinements to the Tacoma plant by Mr. Shuman resulted in 1911 in an engine and boiler which showed considerable strides forward in their design, the ratio of 245 square feet of sunshine per one brake horsepower having been attained.

It may be mentioned here that the pipes constituting the sun boilers have invariably been blackened. For low temperatures, copper black has been used as the absorber, but where high temperatures were required platinum black was used.

Electric Death Traps in Hun's Retreat

I

If you have any doubt that the Teuton is possest of a cunning mind, then you have but to read the reports that have come out now and then from various reliable sources on the battle-fields of Europe, where the Allied troops have always had to contend with much deadlier and more sanguinary affairs, of deadly and inhuman offensive schemes, such as liquid fire and gas, which horribly mutilates and disfigures its victims in thousands of cases. The Allies were never sure of what they might expect when they advanced on enemy territory. The Huns resort to every possible underhand scheme their wily brains could think of in a desperate effort to spread terror among the Allied soldiers, and some of the despicable "traps" used, to make even the most seasoned of our men flinch from the sight of them which we have not the space here to describe, are illustrated herewith.

Fig. 1 shows how the Germans often mined the town pump, or any other pumps on which they could operate, so that when a thirsty Allied soldier endeavored to draw some water, he would be instantly killed by a charge of gas set off by an electric contact and battery inside the pump, the fuse circuit being closed on the first downwallowing of the handle. Of course, hundreds of mechanical traps were used, as well as electrical ones. The electrocuting has been extensively used in these operations, a simple affair, and comprises nothing more than a small dry battery or other battery, together with a pair of electric contacts arranged to be closed by the current of water running off a piece of fuse wire, and a piece of fine fuse wire which is placed in the explosive. When the water shorted the contacts, the electric current passed through the fuse wire, and through the fuse wire with the fuse wire, and destroying the fuse wire, the current would pass through the fuse wire, and through the fuse wire, and destroying the fuse wire, and destroying the fuse wire, and destroying the fuse wire, and destroying the fuse wire, and destroying the fuse wire, and (For Description See Opposite Page)
Submarines in Peace-time

Now that the great world cataclysm is practically over, we have to think of many reconstruction problems, and one of these will undoubtedly have to do with many of the marine as well as military apparatus which have been developed and built in unbelievable quantities. For one thing, the flotilla of submarines—especially surrendered U-boats. A New York inventor, Mr. George Wall, has proposed and here illustrated a novel use for these superfluous submarines, namely, to utilize them as freight carriers, and not only to perform this service in the ordinary sense, as has been done when the giant submarine "Deutschland" crossed the Atlantic Ocean with a cargo, but to arrange for these submarines to pass thru a submarine tunnel for example. Let us consider, as Mr. Wall points out, the freight-handling problem at Manhattan Island, New York, where incoming steamers are unloading their cargo and are老爷.

Telephoning To and From Moving Trains

Three Americans residing in Toronto, Canada, Messrs. Isidor, Abraham and Samuel Berliner, have invented a moving train telephone apparatus for telephoning to and from trains en route, as depicted in the illustration. This apparatus permits voice transmission to be made automatically and directly thru the ordinary car wheel and axle, without the assistance of any contributing medium, by a special instrument connected to the wheel. Thus electrical connection between the instrument and the rail is made thru the car wheels, and in combination with the ordinary rails properly bonded for the block-signal system, but it will work equally well on any track where the rails are similarly bonded, without regard to the absence or presence of a block-signal installation.

Telephonic speech or voice transmission is conducted thru the ordinary existing axle, thru the wheels and down to the rails, along which it runs and is picked up by other moving trains or any of its desired joined cars, train dispatcher's offices, signal towers, stations, city exchanges, towns, villages, hamlets, or with that of any regular telephone subscriber. This railroad telephone invention consists of an apparatus including standard equipment only comprising the well-known telephonic retardation or repeating coils, ordinary rolling stock of wheels and axle, requisite bearing instrument from which it is connected to the wheels, and the usual rails, properly bonded. This transmission and reception is carried on, it is claimed, without regard to the trains' speeds or of trains moving in the same direction, opposite directions, trains crossing over at right angles to another, or any other moving positions, whatever these be upon the same track as in the case of a fixed track line, or between any tracks.

The control of the system differs in no respect from ordinary telephone operation, and artificial amplifiers requiring delicate adjustment are not employed. The invention now makes it possible for a connection to be made between the train instrument and that of any regular telephone subscriber. Train speed is of no material consequence, for the same results are attained to travel at 60 miles an hour as when barely moving.

Telephoning Between a Moving Train, Irrespective of Its Speed, and Any First Station, Office, or Home, Is Now Possible—Thanks to a Recent Invention, Which Enables the Telephonic Currents to Travel Thru the Car Wheels and Along the Rails to the Nearest Telephone Exchange.
Submarines in Peace-time

loaded in some cases on the piers at the North River. This freight is frequently trans-shipped by auto-truck or otherwise to points directly across the city. In other words, the goods are often carried thrice to any point of the city. The conversation may be held as easily as from house to house. The word of the voice is just as clear as with the telephone on a city circuit. One cannot tell that the train is moving, as far as the sound in the instrument is concerned, it is claimed.

A working model of a new moving train telephone apparatus has been very successfully demonstrated by the Canadian Government Railways on their road by Mr. W. W. MacFarlane of New York, who conducted the tests of his invention, which was tested at Moncton, N. B., Canada, from July 16, 1917, to March 28, 1918, inclusive.

During these tests, which were very complete, the conversations were carried on between the train and the dispatcher’s office in a clear and distinct manner.

The engine was cut off from the car and proceeded a mile down the track by orders telephoned from the conductor to the engineer. The engine was then stopt by telephone orders from the conductor, who was on the car, and instructed to come back and couple up again. Then an order was given by the conductor to back up the train and take on the flagman, who had gone back to flag.

Before backing up, a telephonic message was sent to the dispatcher’s office, asking if it was safe to back up, and the answer by telephonic from the dispatcher was that this would be all right. After backing up to the flagman, the order was received from the dispatcher’s office to go ahead to Humphreys and cross over to the other track and come back to Moncton. Before reaching Humphreys a second telephonic message was received from the dispatcher countermanding the previous order to cross over, but return to Moncton on the same track, as the train was protected from the rear.

All these instructions were transmitted by telephone from the dispatcher’s office to the conductor on the car and by him transmitted to the engineer by telephone, while the car was running, showing that it is perfectly feasible to control a moving train by telephone from the dispatcher’s office at a distant point. The invention is patented in the United States and Canada as well as in foreign countries. This new railroad telephone system promises to completely revolutionize modern railroading.

INDIAN PRINCESS LEARNS WIRELESS.

The accompanying photograph shows an Indian princess learning wireless telegraphy—Miss Emily Moran, descendant of a famous Indian chief. She promptly offered her services to her country in this national crisis, and is rapidly learning the art of radio operating so that she can graduate from clerical work to the wireless room of an ocean liner or possibly a transport.

Many young women have taken up wireless operating, several of the leading schools having classes, at which young ladies attend. At the present time there has not been a very large opportunity to place these fair radio graduates, because the Navy Department controls all the wireless stations, and it is against their rules to have women in any government radio stations. However, there are many ways in which women trained as radio operators can help and have been helping. For one thing, they can be of considerable aid in helping to teach the soldier and sailor "cookies" the rudiments of radio operating—particularly the code, which is always a great stumbling block to most of them. Women should prove particularly efficient in teaching this part of the radio art, for they have proven themselves very adept and successful in imparting knowledge to students of all ages in our public schools without the country.
A New Aërial Smoke Barrage

The airplane has surely come into its own during the recent world war. Hundreds of planes were to be seen in the air on various sections of the great battlefield at many times during the day, their glistening wings sparkling in the bright sunshine. Pursuer and pursued hurtled thru the air at prodigious speeds. These airplane attacks looked all very tame from the ground until one of them closed in on his adversary, when many a spectacular battle was enacted. Perhaps one of the most spectacular of all aerial battles is that mentioned in a number of the interesting stories that have come to us from the iron-hearted flyers of the air, where an enemy plane has dropped out of the cloud, in order to pounce down and surprise an unsuspecting flier below. Some of the German aviators used to practise this trick regularly, sailing upward thousands of feet, only to suddenly disappear in the cloud or cloud bank. Then the crafty flier would suddenly dart out of the cloud at the side or at the bottom, and if a hostile plane happened to be anywhere in the vicinity, the factor of surprise would in practically all cases be on the side of the emerging warplane.

But clouds would not always be conveniently at hand for carrying on such maneuvers. There is not always a cloud to be found in the vicinity of the battlefield. In the case of the aerial warfare—the "airplane smoke producer"—the particular form of this invention here illustrated and described being due to John Koltsko, of Watertown, Connecticut.

As the front cover and accompanying views show, this invention enables an aviator to send out a large quantity of heavy smoke which will entirely envelop the plane and prevent, or at least make it extremely difficult for, an enemy plane to "plant" a good shot on him. This is more apparent when it is considered that the smoke would not simply have a dense cloud of smoke blown around it at one point in the air, but it would in a few minutes produce a long trailing cloud of black smoke, and it would indeed be quite difficult for an aviator to tell at exactly what point in this cloud the enemy plane was.

The technical details of this smoke-producing apparatus for aircraft are quite simple and it operates as follows: A steel tank is mounted in the body of the plane, from which there is connected a bypass pipe connecting with the exhaust of the engine. A suitable valve control is provided to pass smoke from the motor exhaust into the tank. The tank contains certain chemicals which when acted upon by the fumes from the motor exhaust, produce smoke rapidly in great volume.

As the illustration shows, the diffusing heads consist of conically-shaped drums with perforated faces on them, and are placed around various parts of the airplane, under the wings and along the fuselage.

THE MAGNETIC SURVEY VESSEL, "CARNEGIE." The Magnetic Survey Vessel, Carnegie, arrived safely at her home port, Washington, D. C., a short time ago, where she was put out of commission during the period of the winter famous cruise from Buenos Aires, Argentina, round the Horn of Valparaiso, Chile, Callao, Peru, thence thru the Panama Canal to Newport News, and in command of Dr. N. W. Edmonds and a number of other scientists of the Government staff.

Copyright, 1918, by E. P. Co.
ACKED by an absorbing story enacted and assisted by elaborate scenic and stage effects, "The Long Dash" has proven one of New York's latest and greatest theatrical successes. The play was written by Robert Mears MacKay and Victor Mapes, co-author of "The Boomerang." It has a distinguished cast, including Robert Edeson, Henry E. Dixey, Violet Kemble Cooper, Milicent Evans, and others. The dramatic story revolves around the invention of a marvelous new "radio controlled" cannon. The secret of its operation is stolen by a spy. With the inventor of the gun dead and the radio code by which the gun is operated lost, many curious and exciting incidents result. Interspersed with all these affairs there is a delightful love story in which two brothers, Paul and John Hazelton, both impersonated by Robert Edeson, are concerned.

Now for the dirty work. Those who have seen this show have undoubtedly wondered just how the wireless controlled gun, a large sized and faithfully reproduced model of which is used on the stage, as the accompanying photographs show, is operated. For it surely does give one, no matter how sophisticated in scientific matters he may be, a genuine dramatic thrill. Robert Edeson, who endeavors to solve the mystery of the lost code, presses the key of the wireless transmitter located across the stage from the gun, and every time he presses the key a crashing blue-white spark several inches long leaps across the spark gap at the transmitting apparatus. A similar spark also appears simultaneously at the spark gap fitted on the gun pedestal. Being of a scientific turn of mind, he eventually gets down to the point where he can cause the gun to train around a circle, and also up and down vertically, besides firing. The controlling signals comprise a number of dots or short sparks, and after the proper number of these have been transmitted, a long dash or spark is required to cause the particular function in hand to take shape. Thus when the gun is to be fired, after being trained with a previous set of signals or sparks, a number of short flashes are rapidly transmitted, and then the "long dash" or spark is the signal that the gun will fire. A thirty-eight caliber Colt revolver is cleverly arranged inside of the model cannon and this, operated by a stage assistant, produces the explosion whenever the gun is fired.

But this is not all, for to lend still more enchantment to the seeming mystery of this pseudo-scientific drama, the target at the rear of the stage plays a very important role. For every time the gun operates another "bullet" goes thru the target. At least the audience thinks so, for does not a hole appear in the target each time the gun fires? Sure it does, and little Willie in the front row as well as his grand-dad probably wonders how in the dickens they can fire a small naval cannon right on the stage and cause a shell to pass thru the target without killing a few dozen actors standing off stage. The truth is, there "ain't no such animal" as a bullet used, but a trusty assistant stands ready with a string in his hand, and each time the gun fires he yanks another wad of paper out of a previously prepared hole in the bull's-eye of the target. "Ye gods!" little Willie remarks, Mr. Edeson is sure some sharp-shooter, and in truth he is, so far as the story of the drama is concerned.

As will be recollected, in the introduction it was mentioned that Mr. Edeson impersonates two roles—that of Paul Hazelton as well as John Hazelton. In another act a clever bit of stage work is carried out, and a few words describing it will undoubtedly prove of interest. In this scene one of the brothers sits down in a large high-backed, old-fashioned chair, and presently turns the chair with its back to the audience and starts eating at a table. The audience sees the actor's arms moving as he proceeds to eat his dinner, but the old saying that the "hand is quicker than the eye" still holds good to a dot, for right before your very eyes and while the good Mr. Hazelton No. 1 apparently is enjoying his meal an unseen transposition takes place in a few seconds. The seat of the chair is a spring-actuated affair and collapses when desired. The actor escapes down thru the bottom of the chair by means of an electrically operated dumb-waiter, or "trap," as it is called in stage parlance, and another actor rises on the trap, gets into the chair and carries on the arm movements and other embellishments that go with the assimilation of a hearty repast; and in the meantime the door of the room opens, and in walks the other brother, Mr. Hazelton No. 2, who is no other than our old friend, Mr. Robert Edeson.

An electrically controlled machine for sorting coffee beans has been invented by a native of Munich.

India has increased its annual coal production to 12,000,000 tons and is introducing electrical machinery into some mines.
Nikola Tesla and His Inventions
By H. Gernsback

AN ANNOUNCEMENT

Several years ago, in the course of a discussion, a well-known journalist asked me whom I considered at present the world's greatest inventor. I said: "If you mean the man who really invented, in other words, originated and discovered—not merely improved what had already been invented by others, then without a shade of doubt, Nikola Tesla is the world's greatest inventor, not only at present, but in all history."

My friend was much surprised and voiced his astonishment. "Surely," said he, "you do not mean to place Tesla ahead of such great men as Archimedes, Faraday or Edison?"

"That is exactly what I mean," I replied, "and before twenty-five years have elapsed the world at large will echo my opinion."

"But listen," persisted my friend, "who on earth is this man Tesla anyway? What are his wonderful inventions, what great thing has he ever done? How is it that the world at large does not know him?"

"To begin with, and the better to impress you," I replied, "Tesla has secured more than one hundred patents on inventions, many of which have proved revolutionary. Science accords to him over 75 original discoveries, not mere mechanical improvements. Tesla is an originator in the sense that Faraday was an originator. Like the latter he is a pioneer blazing the trail; aside from this he is a discoverer of the very highest order."

"Ninety percent of the entire electrical industry pays tribute to his genius. All electrical machinery using or generating alternating current is due to Tesla. High tension current transmission without which our long distance trolley cars, our electrified trolleys, our subways would be impossible, are due to the genius of Tesla. The Tesla Induction Motor, the Tesla Rotary Converter, the Tesla Phase System of Power Transmission, the Tesla Steam and Gas Turbine and the Tesla Coil and Oscillation Transformer are perhaps his better known inventions."

"As to your last question, namely, why the world at large does not know Tesla, it is answered best by stating that he has committed the unpardonable crime of not having a permanent press agent to shout his greatness from the housetops. Then, too, most of Tesla's inventions, at least to the public mind, are more or less intangible on account of the fact that they are very technical and, therefore, do not catch the popular imagination, as, for instance, wireless, the X-ray, the airplane, or the telephone."

The trouble with Nikola Tesla is that he lives a century ahead of his time. He has often been denounced as a dreamer even by well informed men. He has been called crazy by others who ought to know better. For Tesla talks in a language that most of us do not as yet understand. But as the years roll on Science more and more appreciates his greatness, and begins to pay him tribute more and more.

In 1893, three years prior to the earliest attempts in Hertz wave telegraphy, Tesla first described his wireless system and took out patents on a number of novel devices which were then but imperfectly understood. Even the electrical world at large laughed at these patents. But large wireless interests had to pay him tribute in the form of real money, because his "fool" patents were recognized to be fundamental. He actually antedated every important wireless invention.

A few weeks ago the world read thru news dispatches of a great wireless discovery—the static eliminator. But Tesla had not only patented systems overcoming this and other forms of interference but had actually constructed and successfully operated devices years ago in Colorado, under conditions where static interference was troublesome to an extraordinary degree. A photograph of one form of his apparatus is published with a note from him for the first time elsewhere in this issue of the Electrical Experimenter. And so it goes. The world smiles at an unbelievable smile, but Tesla's master mind invariably sets the world aright.

I first read about Tesla in a well-known German weekly publication when I was less than 15 years old. The Editor of that publication reproduced his picture on a full page and paid high tribute to Tesla, hailing him as the world's coming greatest electrician.

H. W. Buck, Chief Engineer, President of the American Institute of Electrical Engineers, among others, said: "The work of Nikola Tesla in his great conception of his rotary field seems to me one of the greatest feats of imagination which has ever been attained by human mind."

Lord Kelvin, before the British Association, commenting upon the Tesla Transformer exhibited, said: "This is a wonderful development of the induction coil destined to be of great importance."

Electrical Review, commenting upon the wireless: "Mr. Tesla's
researches in this field have attracted world-wide attention, and his is undoubtedly the master mind."

_Der Elektro-Technische Anzeiger, Berlin, and Elektrizität, Leipzig_, Germany, (commenting upon Tesla's work): "It is a combination of the grandest power of technical performance with the most vivid imagination, such as has never before manifested itself in the human mind."

Brigadier Allen, of the United States War Department (commenting upon Tesla's Turbine): "Something new in the world. Officers are greatly impressed with it."

While studying abroad I read every scrap of his work I could lay my hands on. I performed most of his high frequency experiments, and the more I saw of his work the more impart I became. Some years ago as Editor of _Modern Electrics_, I met him in a New York shop where his famous turbine models were first built. I was fascinated with the tall, gaunt man, then about 50 years old, but looking less than 30. His extraordinary face, with his deep set blue eyes, proclaimed the intense thinker—the philosopher. A few minutes' chat with him left me more than ever convinced of his greatness.

Further contacts during the past few years still enhanced my opinion of him. Tesla is a man of extraordinary knowledge. He is remarkably well read and has a photographic memory whereby it is possible for him to recite page after page of nearly every classical work, be it Goethe, Voltaire or Shakespeare. He speaks and writes twelve languages. He is an accomplished calculator, who has little use for tables and text-books and holds the sliding rule to contempt and has received numerous honors and distinctions of all kinds. He is a knight of several orders, holder of many titles and diplomas. Some time ago he was awarded the Elliott Cresson gold medal by the Franklin Institute and last year the Edison medal by the American Institute of Electrical Engineers. Many extraordinary distinctions have been offered to him which he has declined. As of timely interest one instance may be mentioned. At the announcement of Tesla's high frequency discoveries, while the former Emperor of Germany was all-powerful and great men were eager for his favors, Tesla received an invitation from him and the Empress to repeat his celebrated experiments at the Royal Palace in Berlin. He forgot all about it and did not answer for one year, when he politely apologized for his inability to avail himself of the honor. Later the invitation was renewed and nearly two years past before Tesla answered to the same effect. After a lapse of time, however, upon the announce-

---

**Nikola Tesla**, in the opinion of authorities, today is conceded to be the greatest inventor of all times. Tesla has more original inventions to his credit than any other man in history. He is considered greater than Archimedes, Faraday, or Edison. His basic, as well as revolutionary, discoveries for sheer audacity have no equal in the annals of the world. His master mind is easily one of the seven wonders of the intellectual world.

_H. Gernsback._

"Dr. Tesla," I said to him, "you are aware of our great admiration for you, which may or may not be important. But the great public knows little of your mark. Even many of those technically educated—excuse the frankness—think that you are

“Odd Photo” Contest

WELL, Readers, what do you think of this perfect galaxy of "Odd Photos"? Fit for a king, eh. That's what we thought and so decided to publish them. Have you ever tried to enter a photo in our "Odd Photo" contest? Now is the time. Just look over this collection, gathered from all parts of the country, and you will gain a clear idea of just what we are after in this direction. We want brainy pictures as well as freak photos. Electrical, Radio and Scientific subjects give you a wide field to choose from. See announcement of "Odd Photo" contest elsewhere in this issue.

WELDING CAR TRACKS AT NIGHT

Herewith is an interesting night picture of men welding car tracks in Buffalo. The welding, of course, is electric, the trolley wire being tapt and a wire fastened to a weight placed on the track, making the connections. The 350 volt current is reduced thru a bank of resistance grids carried on a cart. The men are equipped with a heavy glass mask of special design, to protect their eyes and ears.

Kenneth Strickfaden, New York City.

IS IT AN A. C. OSCILLOGRAM?

I here present a print which resembles an alternating current oscillogram. This, I am told, was caused by the film being wound too fast, thereby causing static electricity.

What caused the lines to be in double or in pairs? Can anyone explain this?

What causes the lines to have those peculiar peaks?

I hope that your readers can answer it.

Wm. P. Ullrich, Ansonia, Conn.

LIGHTNING AT THE SEASHORE

Here is an excellent photograph of an electrical storm at the seashore.

Last August, while at the seashore, I was awakened about 1 A.M. by the loud crashes of a storm. The flashes were very bright, so I got out my camera. Herewith is the best picture I obtained. In the foreground is a boys' camp and the board walls. The beach can be made out very clearly.

C. M. Fairbanks, Ocean City, N. J.

MYSTIC SHADOWS CAST BY SOLAR ECLIPSE

One of the many interesting phenomena occasioned by a partial eclipse of the sun is the shape of the shadows cast by the light filtering thru the trees. The present picture is one taken during the eclipse of June the eighth, at a spot where the eclipse was 89 per cent. The picture is of a sheet images of the sun on this particular occasion.

James L. Clifford, Evansville, Ind.

A 2-HEADED MAN

The photo herewith, altho it does not bear any relation to electricity or radio, you will admit is odd. It is prized especially because of its history. The photo itself is a duplicate of my homely physiognomy and was taken under several difficulties. In the first place I was home with the mumps and the measles and, being at a loss for something to do, I started to pester my peaceful camera. Secondly, I was alone and had to take the picture myself. Thirdly, my camera is a box type, and I had to rig up a series of wire rings, so

New British 'Plane Can Coast 20 Miles to Safety

In a recent report from an aviation camp behind the British lines in France comes the news that while the absolute proof airplane has possibly not yet been invented, in the opinion of American pilots who are except for slight damages which may follow a landing. They are so balanced and the wings so arranged that when the engine stops, they glide gradually and easily to earth, without the pilot's attention.

The following test shows how remarkably stable these airplanes are: A pilot climbed to a sufficient height, stopped his engine and took his hands off the controls, merely keeping his feet on the rudder bar. He steered for an airdrome twenty miles away and, except for keeping it straight, let the airplane do what it liked. It traveled the whole twenty miles as steadily as a bicycle coasting down a long, straight and gentle hill.

The accompanying illustration shows just what such a performance means to the aviator, who has heretofore always been in danger of being forced to volplane down at a sharp angle as soon as the engine stopped. Thus the aviator had to make a landing while coming down at a fairly sharp angle, and in some cases the plane has practically "dropt out of the sky," killing the aviator and demolishing the machine.

Just think what it will mean to the bird-men when they can volplane down a distance of twenty miles, such as from Mineola, L. I., to Governor's Island, or vice versa. It's really a wonder our flying machine inventors have not perfected such a device before this, when we stop to think of the many military aviators who have had their engines stall when over the German lines, which invariably meant they had to descend in enemy territory, with subsequent capture. The cities and towns shown about New York City in the accompanying view are all situated approximately 20 miles distant.

Electrical apparatus taking current from a light socket has been invented by a French scientist to purify the air in a room by literally pumping it into a reservoir and washing it.

The One Great Problem Confronting the Flying World Has Always Been—"How Far Can I Glide or Coast, if My Engine Should Stop?" The Answer Is—Twenty Miles; that is, If You Have One of These Newest British Planes, One of Which Has Glided That Distance in an Actual Test.
New Flashlight Cuts Off After One Minute

The newly invented and extremely novel electrical flashlight here illustrated incorporates a feature not possess by any other flashlight so far developed, in that when the push button is depressed the lamp circuit is kept closed for a predetermined and specific length of time, such as one minute, and then opens the circuit automatically. This feature results in a great saving of battery energy, particularly in such forms of the dry battery electric lamp as those made in the form of an ordinary lantern, of which are provided with a switch instead of a push button, and which the owners thereof have a great habit of thinking that because it is an electric lantern, it will stand almost any abuse. It would make the heart of any good electrician with extreme anxiety to watch some users of these electric lanterns and see them close the switch and then forget it—as dry battery to them is a veritable electric dynamo; they never give a thought to the fact that the dry cells used in every one of these flashlights, will give several—several—times the life if open the switch or button periodically—say at intervals of one-quarter to one-half minute—in order to give the battery a chance to recuperate.

It is to guard against just such misuses of the electric flashlight that the inventor of the present automatic cut-off push button, Mr. G. H. Parsons of Stanmore, Conn., has evolved and patented the device here illustrated. One illustration shows the exterior of his new flashlight under the "Tempolight," while the second illustration shows a diagrammatic view of the interior arrangements. These are simple and comprise the usual lamp bulb, a dry cell, and a circuit-closer or push button, to which he attaches a small air bellows. When the button is depressed this bellows is also depressed, and the air exhausted within it. By means of a slow acting air valve or other suitable arrangement, the bellows after an appreciable length of time of one-half to one minute, depending upon the period for which the switch is set to expand and open the push button contact trigger. A spiral spring on the push button rod tends always to push it outward.

You Push the Button of This Flashlight—a Minute Later It Extinguishes Itself Automatically. Result—a Saving in Battery Power and Life.

FOOLING THE DRAFT BOARD?—IT CAN'T BE DONE.

The sad and distressing fact has been brought forth that to escape a righteous duty, one that every full-blooded American should be proud to fulfill, there are amongst us mor- tals in this free land, a new generation—small in numbers, to be sure—who deliberately seek to evade the greatest of all things—the protection of the Stars and Stripes and the preservation of the Union. Amongst the false claims is that of partial or total deafness.

The French military specialists have already established the difficulty in this direction. It appears that the malingerer most difficult to detect is the one claiming complete loss of hearing in one ear. A moment's thought will show why this should be. Were only partial deafness claimed it would not be difficult to trap him, as he could not possibly be consistent in all his statements through an extended series of tests; but, with complete unilateral deafness as the claim, he simply and uniformly fails in the negative to all tests applied to the alleged defective ear.

Dr. R. R. Brownfield has devised a test which not only definitely determines the acuity of hearing in either ear, but also quickly detects the unilateral malingerer.

The device as evolved by Dr. Brownfield batteries and make-and-break contacts are entirely dispensed with. The ordinary 110 volt alternating commercial lighting current is used. The variable current is produced by a potentiometer, and is variable from an absolute zero to maximum. No vibrating iron is used, and the maximum strength of current employed is dependent on no factor except the ratio of the electrical resistances employed. The circuit current produces 240 vibrations per second, equal to the average tone used in conversation.

The sound producer is similar to a telephone receiver except in one very important respect—the core is of soft iron and is not magnetized. This results in eliminating the variability due to demagnetization and doubles the pitch, so that the ordinary 240 vibrations per second are increased to 480 vibrations per second. This, it is claimed, makes the test more difficult to pass. The sound producer is to the usual telephone receiver as a telephone is to the usual radio receiver.

The sound producer is provided with three lugs to hold it away from the ear, so that the sound will be transmitted solely by air conduction. By simply turning the indicator from 100 to zero, one can cause the sound to increase from the point at which it is just perceptible to one of normal hearing, the threshold of audibility, or 100 per cent, acuity, to a degree of intensity at which failure to perceive it indicates that the subject has no practical hearing. In addition to the variable receiver, there is a sub-judicatory one that always operates at maximum intensity, irrespective of the loudness of the other.

In the usual test for the acuity of hearing, only the variable receiver is used. As the subject holds this to the ear, the pointer is gradually moved from zero to a point on the scale is reached, that would normally indicate very defective or almost no hearing for the good ear.

The very nature of the test, it will be noted facilitates the detection of fraud, because the better he can hear in the alleged defective ear, the less he will hear in the other—a condition just the opposite of what he is supposed to be; with the intensity of sound increasing, the less he will hear under these conditions the sound appears to come in some mysterious way from a point at the center of the head; and if the two ears are approximately equal in acuity, there is absolutely no possibility of identifying the gradually increasing sound in the supposedly good ear until a point is reached on the scale away beyond the reading that would be obtained when the loud receiver is disconnected. Hence in the case of the pretender, the physician has only to repeat the test with the loud receiver disconnected, and a totally different reading will be secured, thus proving the deceit.
Wintertime Uses for the Electric Fan

By PAULINE GINSBERG

As it ever occurred to you that the electric fan can be used to great advantage in the wintertime as a labor and time saver? Probably it has not. This is but natural on account of the popular idea that the fan has only one mission, that of cooling the air. What the fan really does is to circulate it. By impelling circulation, for instance, about the body, the displacement of the warm air for the cooler, as well as surface evaporation accordingly gives a cooling sensation, but in hot weather such as in July, the forced air from the fan does not change for the cooler, it being equally warm both indoors and out and the fan sometimes causes more discomfort than comfort. As many of us have entertained the idea that the fan brings the air, naturally the fan was invariably hustled to a secluded nook in the attic or down the cellar until the warm zephyrs of the next spring reminded us that it was "fan-time" again.

A few suggestions are here given for the wintertime utility of electric fans, and eventually you will find a number of other uses to which the electric fan can be employed with benefit.

When the master of the house (or was it the janitor?) goes down to the cellar, and after much ado about the furnace (no, not "nothing"), finally makes a heroic attempt at starting a fire on a sultry day and it won't work—what to do for a forced draft? Just apply a fan opposite the front or side ashpit door of the furnace as here illustrated, and the fire will soon be crackling away merrily. Along this same line of the heating problem it can often be placed behind or in front of the steam radiator to circulate the air around and thru it so that the room is heated more rapidly and evenly.

Something that many women will appreciate is the use of the fan in the laundry for drying clothes. You will notice, in the third photograph, how the fan is placed away from the clothes lines in order to give a freer circulation of air so that it passes over all the clothes, and has therefore almost the effect of a light wind were the clothes outdoors. If the windows are kept open both at the top and bottom, you will be surprised how nicely they will dry.

The fan in the kitchen window solves a problem that confronts every housewife—what to do to prevent cooking odors and smoke from spreading over the whole house? It is particularly annoying when friends pay a visit. Any handy piece of board the length of the window can be attached as a shelf. It should be about three-quarters of an inch thick and can be fastened in place with a pair of brackets and a few screws. On this the fan is placed so as to face the open window and create a strong suction. In a short time the smoke and odors will have vanished. Also to deodorize the kitchen a flower or two may adorn the other end of the shelf.

Something we all dislike is the unpleasant odor that is the result of a room or rooms having just been painted. With the window kept open a few inches at the top and bottom and with our friend, the electric fan, kept going, the paint will dry quickly and the odor will have vanished in a much shorter time than had it not been used. Incidentally dust will have been prevented from settling on the wet paint; also, if having dried more quickly, there will be no marked luster added on the painted surface. The fan can also be played on any small article that has been painted or enameled, such as a kitchen chair or table.

Gas heaters were never in such favor as they are last year and will be this year (the coal problem still being the chief reason). As a rule, with the oncoming of a substitute, some unfavorable feature is bound to spring up—in this case the reduction of humidity—the gas flame consuming a high percentage of the precious vapor which contains the oxygen, so necessary to our lungs. The electric fan again clears the situation.

Place a pan about three-quarters full of water anywhere convenient, so that the fan can play directly on it. Over the pan put a thin board or piece of heavy cardboard, which has been perforated a number of times, so that small wicks or pieces of cloth can be smeared into the perforations. They should be long enough to pass down into the water. The board or cardboard should be of the correct size so as to exactly suit the handles, and so be held in position; it should not be blown off by the fan. The arrangement need not necessarily be kept for a great length of time in one room, but it can be employed for a short period in every room, especially in bedrooms and sick rooms, to promote comfort and good respiration, which in turn produce sound healthful sleep.

A fan should invariably be kept in the sick room so as to insure good ventilation. It should of course be turned away, and at a considerable distance from the patient. It will greatly ease his suffering and discomfort which come from the difficulty of breathing and from the inability to sleep. The fan can be kept going at intervals near a slightly lowered window. As the impure air rises and escapes thru the upper opening of the window, and the pure air enters thru the lower section, a good plan would be to have a small funnel made to hold the fan near the upper opening, the suction pumping out the impure air. It should also

(Continued on page 654)
THE most beautiful object in the midnight sky during these winter months is the planet Jupiter, which will continue to be in excellent position for observation far into the spring. Upon New Year's Day Jupiter will be in opposition to the sun and therefore directly on the meridian at midnight. It is then seen at its best and will be visible throughout the night, rising in the east as the sun sets and setting in the west at sunrise.

Jupiter shines by reflected sunlight with twice the brilliancy of the brightest of the stars, Sirius. When seen during the midnight hours the remarkable, unflinckering brightness of this largest and most distinguished member of the solar system at once serves to set it apart from the scintillating stars far beyond.

There is but one planet, Venus, that surpasses Jupiter in brilliancy, and as Venus never departs more than forty-eight degrees from the sun Jupiter always shines without a rival at midnight. To one who has observed the two planets together the silvery radiance and surpassing brilliancy of Venus, due not to its size, but to its comparative nearness to the earth, at once serves to distinguish it from the golden yellow glow of Jupiter.

Even the smallest telescopes of two or three inch aperture will show the four historic moons of Jupiter which were the first celestial objects to be discovered when Galileo turned his crude telescope to the heavens in the year 1610.

The fact that these tiny points of light were actually revolving around the great planet was soon detected by the famous astronomer and we can imagine with what breathless interest he observed these satellites of another world whose discovery dealt such a severe blow to the old Ptolemaic theory that the earth was the center of the universe. It was not until the great telescopes of modern times were invented that the five additional moons of Jupiter were discovered. The four satellites first observed by Galileo were fancifully named Io, Europa, Ganymede and Callisto, in the order of their distances outward from the planet, but these names are rarely used now, the satellites being designated for convenience I, II, III and IV, respectively. The first of the new satellites to be discovered was Satellite V, which is the nearest to Jupiter of all the nine moons. It is an extremely small body, not more than one hundred miles in diameter, and to discover this tiny body as it skirred rapidly around the great planet within sixty-seven thousand miles of its surface, nearly lost in the glaring rays, was a diffi-
cult feat even for an experienced observer. It was accomplished, however, by Prof. Barnard with the great Lick refractor in 1899. Saturn IV is hopelessly beyond the reach of any but the greatest telescopes, as are also the four satellites discovered since that date. In fact, most of these tiny moons are observed photographically. Satellites VI and VII were discovered photographically in 1905. They are both about seven million miles from the planet, their paths loop thru one another; they are, moreover, highly inclined to each other at an angle of nearly thirty degrees. When nearest together they are separated by a distance of two million miles. Two more extremely small bodies, known as Satellites VIII and IX, have been discovered quite recently, one at Greenwich, England, in 1908, the other at the Lick Observatory in 1914. These excessively faint bodies are the most remote satellites of Jupiter and they are of particular interest because they travel around the planet in a direction opposite to the direction of revolution prevailing in the solar system. The ninth and most distant satellite of Saturn also retrogrades; that is, it revolves in a clockwise rather than a counter-clockwise direction around the planet. One explanation given for this peculiarity of the outermost satellites of Jupiter and Saturn is that the backward revolution around the planet is more stable when the satellites are at great distances from the primary and the gravitational control that the planet exerts, therefore weak. The moons of the planets are, of course, subject to the attraction of the sun as well as to the attraction of the controlling planet, and the greater the distance of the satellite from the planet the stronger the pull exerted by the sun and the weaker the bonds that bind such a moon to the planet. Beyond a certain limit it would be impossible for the planet to hold the satellite against the sun’s greater attraction and it would leave the planet to revolve directly around the sun, thereby becoming a planet. It appears that in this manner it is not unusual for the satellite to “back” around the planet than to follow the usual “west to east” direction of revolution. The eighth satellite of Jupiter is the largest, and the ninth more than fifteen million miles from the parent planet and they require about two years and three years, respectively, to complete one trip around Jupiter. When we consider that Satellite V darts around the planet in less than twelve hours at a distance of only sixty-seven thousand miles from its surface we realize what tremendous differences exist in the distances and periods of revolution of the nine moons. There is also great disparity in the sizes of the various moons. The five moons discovered in modern times are all excessively faint and therefore extremely small. The diameter of the largest of these, Satellite V, is less than one hundred miles. On the other hand, the four historic moons of Jupiter are of planetary dimensions. The smallest, Satellite II, is slightly larger than our own moon, while the largest, Satellite III, has a diameter according to measurements made with the 40 in. Yerkes refractor in 1916, of three thousand nine hundred and eight miles, which is only four hundred miles less than the diameter of Mars. The periods of revolution of these four satellites range from one day and eighteen hours for the nearest, which is about two hundred and sixty-one thousand miles from the center of Jupiter, to six days and sixteen and one-half hours for the most distant, which is more than one million one hundred and sixty thousand miles from the planet. These four moons of Jupiter are most interesting members of the solar system. They are so near to the great planet that they are continually dipping into his huge shadow and experiencing an eclipse of the sun’s rays, which, owing to the nearness and great size of Jupiter, lasts for two or three hours. At times of eclipse the moon suddenly disappears from the observer’s view, tho it may be considerably to one side of the planet. Its reappearance later on is just as sudden, or it may pass out of the shadow while hidden from us behind the disc of the planet, in which case its reappearance is invisible from the earth. The occultations of the satellites, or, in other words, their disappearance behind the planet’s disc, are also interesting phenomena to observe, as are their “transits” across the disc of the planet as the satellite passes in front of the planet. Not only the satellite itself but its shadow as well can be seen, a small black dot passing over the surface of Jupiter. The satellite is totally eclipsing the sun for this small dark portion of the planet. Two satellites and their shadows are frequently seen crossing the face of the planet at the same time. It is possible to observe all the phenomena of the satellites’ transits and shadows, eclipses and occultations with very small telescopes. From observations of the eclipses of Jupiter’s satellites the important discovery of the finite velocity of light was first made as far back as the year 1675.

Faint surface markings have been made out at certain times on the largest of the four satellites, Satellite III, and also on Satellite I, or Io. Observations of the markings on the former seem to indicate that it always kept facing Jupiter. They turn toward Jupiter as does our own moon toward the earth.

There are also reasons for believing that the equatorial regions of Satellite I are light colored and the polar regions dark. (Continued on page 668)
An All-Electric Hot Air Balloon

The captive balloon as used by the Allied armies at the present time is invariably filled with hydrogen or other gas supplied from steel bottles containing this gas stored at a high pressure, or else it is obtained from manufacturing supply stations on the field. The first balloons ever used—the old "Montgolfières" of 1783—were made to rise by means of hot air, for, as we all know, and after a short time the heated air rising up into the balloon causes the envelope to become very light and it rises in the air. Some of these balloons will travel for miles, and years ago it was not an uncommon sight in Europe to see hot-air balloons ascend with several men.

There has always been, however, a serious objection to a hot-air balloon where the heater was of the flame or similar type, point to another. Either the automobile engine or a separate gasoline engine mounted on the balloon drives the propeller which supplies current for an electric heater in the balloon. By means of suitable clutches, the engine may be caused to drive the dynamo, or else a current may be connected up to rotate the electric winch drum. The dynamo makes connection to a duplex power cable ready available, and this leads up to the balloon basket.

Also the telephone circuit is carried up to the balloon thru the drum on the other side of the ground where the observer and the observer's balloon are in telephonic connection at all times with the observer's balloon basket, and under battle conditions he would also be in telephonic communication at all times with "field headquarters," so as to report the position of enemy guns, troops, etc.

Referring to the balloon in detail, we find that it is provided with an electric grid heater, and also a motor-driven blower and connecting tube, so that whenever the blower is operated air is pumped up into the balloon envelope, the air passing thru the electric grid heater. The balloon bag is fitted with a suitable damper in the lower opening and a relief valve at the top in the usual manner, the relief valve being connected to the observer's basket by means of a small rope. When it is desired to descend, the observer may open the motor blower switch in the basket, and thus aid the hauling in of the balloon, for as the temperature of the air within the balloon bag falls the balloon naturally tends to descend toward the earth.

8,700,000 American Homes Lighted by Electricity.

From the compilation made by the Society for Electrical Development it is shown that there are 20,689,000 families in this country, of which 17,000,000 have incomes of $500 or more. However, the yearly average family income before the war was under $300.

Over 13,000,000 families are too poor, too illiterate, or otherwise unfitted to buy electrical goods. Over 8,700,000 homes are electrically lighted and 120,000,000 sockets contain Mazda lamps. In over 30,000,000 homes carbon lamps are used. It is estimated that 9,000,000-10,000,000 of these are empty.

Homes lighted by other means, 15,000,000; some are wired but not connected up; electric service is available in 10,613 communities of the United States, compared with 3,545 communities that are being served with gas.

Electric Searchlight.

Ranges of electric searchlights vary from between one thousand to two thousand yards in foggy weather to ten thousand yards or more when the air is very clear. The average sea range is approximately six thousand yards, but there are cases on record where ships have been spotted at a distance of nine miles. These figures are based on a sixty-inch mirror and a twenty-thousand watt arc.
The City of Splendid Night

By AMOS STOTE

A 20th Century poet strolled at night en-raptrured thru the highways and byways of Manhattan, aglow in all her nocturnal glory—not one night, but many nights—some moonlit, others rainy, but always—the magic of millions of electric lights threw its spell over him. And as he walked along this street or that, or mayhap thru the park, or along the shimmering Hudson, the very soul of the city seemed to commune with him. The poet’s name was Amos Stote, and he has here set down three literary gems describing New York City at night as it appealed to him. We like Mr. Stote’s soulful word-pictures of the Greater City electrified—he gives us something to think of besides the lights themselves. Thought is the keystone of all intellectualism. Our poet has given us a new pair of soul spectacles thru which to view many splendid sights—which the everyday man never as much as suspects.

I have wandered down unfavored streets, idle channels from which the thinning traffic of the closing day has been diverted cause—because of a man named Edison. In the old days of shrunkled streets, when darkness threw a mantle of mourning over the city, good men went in groups for safety sake. Then only the brave and the brute cruised singly abroad, for of course we except the gallant, suffering from love’s fever. But now a million gleams of light insure the safety of the streets and give the night-bedecked city over to the amusing glances of those who have learned the beauty that lies in the silent battlements of commerce; and in the old homes and highways.

New York—“the City of Splendid Night.” A Wonderful View of the Theater Section from Times Square—the Hub of Manhattan’s Ever-Seeking Traffic. The Hotel Astor Appears in the Left Foreground.

And a “Night in the Park.” For Within the Sylvan Solitude the Voice of the City Speaks Faintly, and Its Sparkling Eyes Are Veiled with the Romance of Contrast.

Prussianizing the American Ether

By H. Gernsback

W

HEN, on April 6, 1917, the President of the United States, by executive order, closed all wireless stations, the order was carried out to the letter by all Radio amateurs willingly and cheerfully. No notice has come to our attention where an amateur disobeyed the President's wishes.

All amateurs stood solidly behind the President when war was declared because all realized that everyone had to bear great sacrifices willingly and cheerfully. When the armistice was finally signed, the whole world breathed a sigh of relief, including the American amateur who had been given to understand that as soon as peace was actually declared the ether would be free for all once more. The amateurs were satisfied to go back to pre-war conditions, to take up their studies in an art which has few parallels as far as instruction and ennobling of the mind is concerned.

Unfortunately, however, in certain quarters in Washington, a feeling seems to exist that the amateur at best is a nuisance and should be done away with entirely. On November 21st two identical bills were introduced, Senate 5036 and H. R. 1319, the former by Senator Fletcher, the latter by the Honorable Joshua W. Alexander. These bills are reproduced elsewhere in this issue, as well as a statement made out by the Navy Department. The Navy Department frankly admits that these bills are not a war measure and endorses these bills. The Navy Department also makes the extraordinary statement that "experimenters" and scientists will not be interfered with, to wit:

IT SHOULD BE NOTED THAT THIS BILL IS NOT TO CREATE A COMPLETE GOVERNMENT MONOPOLY. THE SCIENTIST, MANUFACTURER, AND SHIP OWNER ARE SPECIALLY PROVIDED FOR, AND NO CHANGE IS PROPOSED IN THEIR STATUS UNDER EXISTING LAW. STATIONS MAY BE LICENSED FOR SPECIAL COMMUNICATION, AND THESE ARE EXEMPTED FROM GOVERNMENT OPERATION.

Any intelligent person reading this paragraph must come to the conclusion that amateurs would revert to their ante bellum days the minute peace was declared by Presidential proclamation.

So far, so good. We now turn to the Alexander and Fletcher identical bills, and read them attentively. To our amazement not a word is mentioned about the amateur. This bill also contains the extraordinary statement that:

"experiment station means a radio station actually used for conducting experiments for the development of the science of radio communication or the apparatus appertaining thereto, and used for no other purpose except as a technical and training school station."

In other words, a technical training school station is an experiment station and vice versa. Of course, this statement alone, unless modified means that if the bill is actually passed by both Houses the amateur will be just as dead as that sensitive spot on a galena detector after it was hit by lightning.

A second reading of the Navy Department's statement also informs us that the President approved a similar bill: H.R. 2572.

We now turn our attention to this bill of Commerce as provided by the act to regulate radio, approved August 13, 1912.

Here the similarity ends. In all other respects the three bills read equally and almost entirely word for word the same. We heartily approve Mr. Padgett's bill, which also has the approval of the President as admitted by the Navy Department.

Now then, as Mr. Padgett's bill was introduced on April 9, 1917, and as Mr. Alexander's bill was introduced on November 21, 1918, one and one-half years later, and inasmuch as Mr. Alexander's bill reads exactly alike word for word all the way through the exception of the paragraphs mentioning amateurs, Mr. Alexander necessarily must have copied Mr. Padgett's bill. But when he came to the paragraph mentioning amateurs he ran his blue pencil right over them.

And that is the joker. President Wilson approves of Mr. Padgett's bill favoring amateurs. Mr. Alexander with the stroke of his pen,—or was it the blue pencil?—wants to shut out all amateurs from the ether forever.

Not that Mr. Alexander is not familiar with the amateurs. He knows them well. Mr. Alexander was the author of the original radio bill before it was a law. The writer in 1912, as will be remembered by amateurs, fought the Alexander bill for the reason that it did not make mention of the amateurs. Finally Mr. Alexander and his advisers were convinced that it would be an injustice to silence the amateurs, and in April of that year the Alexander Wireless Bill died appeared. As will also be remembered, Mr. Alexander and his advisers, accepted the writer's recommendation pertaining to the amateur's editorial in the February, 1912 issue of Modern Electrics, and this bill later in the year was signed by President Taft, thus making it the present wireless law.

It strikes us as remarkable that inasmuch as in 1912 Mr. Alexander could not see the amateurs with an ultra-microscope, his eyesight as far as the amateur is concerned has not grown better in 1918. As soon as we know that there was to be a less wireless measure, we got busy immediately and we found out that there will be a hearing of Mr. Alexander's bill on December 12th which will continue from day to day until about the 12th of the month, it would have been impossible to inform all amateurs of the impending measures, and for this reason we took it upon ourselves to mail out at once some 50,000 letters broadcast to all amateurs giving them the facts of the case.

Of course it is not too late even now for those who have not received our letter. Mr. Alexander's bill has not yet been
past, and we doubt very much if it will. What we want is Mr. Paddet's clauses reinstated—in other words, what we want as far as the amateurs are concerned is the passage of the R.A. This, however, has the full approval of the President, so admitted by the Navy Department; or, what amounts to the same thing we want the Attorney General to insert the same clauses inserted in Mr. Alexander's bill. One is exactly the same as the other. This is all that we want, and it is fair to all concerned. It simply means that the present wireless law is to remain the same, and this, we are certain, will satisfy every amateur in the country.

The licensing system whereby the amateur was licensed by the Department of Commerce for the five years during which the law was in force, proved satisfactory to all concerned. No amateur has ever complained and all the stations licensed the amateurs refrained from sending out false calls or otherwise making a nuisance of themselves, a condition which prevailed before the 1912 wireless law was past.

It has been proved time and again that radio apparatus enormously sharpen the senses of the whole world, no other invention has kept the man away from questionable company during his spare evenings, and this appliance, which few people would have thought could possibly be brought against the amateur. Any parent who has a growing son is thankful for being allowed to spend all his leisure can for radio apparatus, because he realizes more than anyone else that it keeps together the home ties between son and home.

It is not too late as yet to protest against Mr. Alexander's bill, and those who have not as yet done so should write or wire to Mr. Alexander's committee at once. When you write refer to H.R. 13159 and address your letter to the Honorable J. W. Alexander, House of Representatives, Washington, D. C.

A BILL TO FURTHER REGULATE RADIO COMMUNICATION.

Statement by the Navy Department. This has been sent by Lieut. W. H. Fletcher, Chairman of the Senate Committee on Commerce, and by Judge Alexander, Chairman of the House Committee on the Merchant Marine and Fisheries, on November 21, 1918 (S. 890 and H. R. 13159). A similar bill (H. R. 3273) has had the direction of the House Committee on the Marine and Fisheries and the Senate Committee on the Merchant Marine and Fisheries. In general, the bill provides for the acquisition and operation, by the Navy Department, of all radio stations on shore used for commercial purposes by private individuals, and to secure the maintenance and control of the radio service. The Senate Committee has preferred to the adoption of the House Committee.

Radio Law and Existing Restrictions

By William B. Duck

The following interesting article by an attorney well versed in the subject, should answer the thousands of letters with which we, as well as all amateur Radio Supply Houses have been bombarded since Nov. 11th of this year.—

Editor.

Any wireless amateurs never had it so good as now. The new wireless regulations of Congress upon wireless sets, and fewer yet grasped the legal effect of the existing restrictions upon the use of such apparatus.

The existing wireless law derives its authority and likewise its legality from the so-called “except clause” of our national constitution, giving to Congress the right to regulate commerce among the several states. By a simple provision in our constitution, Congress never would have had any authority to legislate upon any phase of this subject. Our national constitution embodies a wide variety of powers given up by the thirteen sovereign states when the constitution was adopted. All other powers and rights were reserved by the states. Consequently when Congress enacts any law purporting to give authority in some provision in the constitution. For instance Congress cannot pass any law regulating the rates of railroads both terminals of which are in the same state. The state only has such authority. Our supreme court has given a very wide interpretation to the word commerce, and the clause of our constitution. It has declared, for instance, that communication carried on by line wires extending from one state into another that is done for a fee, as wireless amateurs have ever bothered to go to the expense of having the courts pass upon the question as to whether Congress has the power to legislate in such a situation for exclusive use between two cities in the same state, if as an incident to this commerce, business is conducted beyond the borders of the state. It is better for the amateurs that Congress compels the higher power amateurs to submit their rights to its decrees in the regulation of their stations.

It is for this reason that the wireless law provides that no license is necessary for governmental operation of these stations. Trans-oceanic radiotelegraphy is not a serious competitor of cables. It will not yet receive from one another all day in all parts of the world, and while signals from radio stations are transmitted in all parts of the world, and the interference with the legitimate work of an installation under government control is most care-ful regulation of radio traffic, through international agreement, can the maximum good be obtained, and only by each nation having the operation of radio stations restricted to the extent of agreements be properly executed.

In spite of the claims of inventors, radio communication is still hampered by atmospheric disturbances commonly termed “static” and by interference. In congested districts, as in the case of important seaports, communication is limited and must be controlled by a central organisation, otherwise a serious situation ensues. In the case of high-power stations where there is a limit to the number of all or wave lengths which can be used, interference is encountered regardless of the control of national stations. For instance a station in Washington is liable to be interfered with by a station in San Francisco, while attempting to receive from France or Italy.

IT SHOULD BE NOTED THAT THIS BILL IS NOT THE MUTUAL RADIO COMMUNICATION GRANT BILL. IT IS ENACTED BY CONGRESS TO MAINTAIN A MONOPOLY. THE SCIENTIST, MANUFACTURER, AMATEUR AND CONSUMER WILL NOT HAVE THE SAME PRIVILEGES HAVING BEEN RESERVED FOR SPECIAL COMMUNICATION, AND THESE PRIVILEGES ARE THE EXCLUSION FROM GOVERNMENT OPERATION.

By agreement with the Department of Commerce, the licensing law, as is now, the licensing of ship stations and of commercial operators for them would be transferred to the Department of Commerce. In the United States, this is a serious monopoly, and although for special communication, these commercial stations would eliminate a number of other stations, the Department of Commerce.

This, however, is not a war measure. In accordance with the act of 1912, all radio stations in the United States, and the use of the submarine in the government's hands, were taken over by the Department in 1917. This now being operated by that Department, promptly in April, 1917. Many changes have occurred during the war, stations formerly operated commercially have been found to be unnecessary for certain purposes, and Section 2 of the act of 1917 is no longer necessary.

The part played by high-power stations in this war and the marked advantage to the Allies, were a party to it, shows very clearly the necessity for Governmental operation of these stations. Trans-oceanic radiotelegraphy is not a serious competitor of cables. It will not yet receive from one another all day in all parts of the world, and while signals from radio stations are transmitted in all parts of the world, and the interference with the legitimate work of an installation under government control is most careful regulation of radio traffic, through international agreement, can the maximum good be obtained, and only by each nation having the operation of radio stations restricted to the extent of agreements be properly executed.

In spite of the claims of inventors, radio communication is still hampered by atmospheric disturbances commonly termed "static" and by interference. In congested districts, as in the case of important seaports, communication is limited and must be controlled by a central organisation, otherwise a serious situation ensues. In the case of high-power stations where there is a limit to the number of all or wave lengths which can be used, interference is encountered regardless of the control of national stations. For instance a station in Washington is liable to be interfered with by a station in San Francisco, while attempting to receive from France or Italy.

(Abridged on page 665)
Conduction of Electricity Thru Gases. Gases, the air included, under normal conditions will not conduct electricity. However, when a high potential is established between two points in a gas, as for example when a Wimshurst machine is excited or a spark coil operated, the gas offers less and hence form shadows when striking an obstruction. In figure 95A c is the cathode. A piece of metal hinged at its lower end stands in the path of the rays. A distinct shadow of the same shape as this obstructing metal is formed at the end of the tube. On dropping the metal down at the hinge by shaking the tube, the shadow disappears.

Experiment 106

In figure 95B the cathode is concave and spherical. The other electrode (anode) consists of a small piece of very thin sheet platinum. The cathode rays are converged, focus on the platinum and are therefore very concentrated. The platinum incandesces, showing the heating effect of the cathode rays. Of far greater importance than either the fluorescent, the shadow, or the heating effect is the magnetic effect, especially as this gives us an insight into the nature of the cathode rays.

Experiment 107

In figure 96 a-b is a fluorescent screen of zinc sulfid, or barium platino-cyanid; c is a mica strip with a narrow slit in it. The cathode rays emerging at d are absorbed by the mica c, except for a small part passing thru the slit. These travel straight thru for the full length of the tube and cause a narrow band of the screen a-b to fluoresce brilliantly. Hence, the path of the rays, which are themselves invisible, is readily seen. If now a horseshoe magnet is brought near the tube the rays are deflected toward it at right angles to the magnetic field. This is precisely what would happen if the cathode rays consisted of very fast electrons moving in a magnetic field.
The Effect of Statics on Wireless Transmission

By NIKOLA TESLA
Written for the ELECTRICAL EXPERIMENTER

A FEW statements regarding these phenomena, in response to a request of the ELECTRICAL EXPERIMENTER, may be useful at the present time in view of the increasing interest and importance of the subject.

The commercial application of the art has led to the construction of larger transmitters and multiplication of their number, greater distances had to be covered and it became imperative to employ receiving devices of ever increasing sensitiveness. All these and other changes have cooperated in emphasizing the trouble and seriously impairing the reliability and value of the plants. To such a degree has this been the case that conservative business men and financiers have come to look upon this method of conveying intelligence as one offering but very limited possibilities, and the Government has deemed it advisable to assume control. This unfortunate state of affairs, fatal to enlistment of capital and healthful competitive development, could have been avoided had electricians not remained to this day under the spell of a delusive theory and had the practical exploiters of this advance not permitted enterprise to outrun technical competence.

With the publication of Dr. Heinrich Hertz's classical researches it was an obvious inference that the dark rays investigated by him could be used for signalling purposes, as those of light in heliography, and the first steps in this direction were made with his apparatus which, in 1896, was found capable of actuating receivers at a distance of a few miles. Three years prior to this, however, in lectures before the Franklin Institute and National Electric Light Association, I had described a wireless system radically opposite to the Hertzian in principle inasmuch as it depended on currents conducted thru the earth instead of on radiations propagated thru the atmosphere, presumably in straight lines.

The apparatus then outlined by me consisted of a transmitter comprising a primary circuit excited from an alternator or equivalent source of electrical energy and a high potential secondary resonant circuit, the terminals of which were used to ground and to an elevated capacity, and a similar tuned receiving circuit including the operative device. On that occasion I express myself confidently on the feasibility of flashing in this manner not only signals to any terrestrial distance but transmitting power in unlimited amounts for all sorts of industrial purposes. The discoveries made and experimental results attained I made with a wireless power-plant erected in 1899, some of which were disclosed in the Century Magazine of June, 1900, and several U. S. patents subsequently granted to me have, I believe, borne out strikingly my foresight. In the meantime the Hertzian arrangements were gradually modified, one feature after another being abandoned, so that now not a vestige of them can be found and my system of four tuned circuits has been universally adopted, not only in its fundamentals but in every detail as the “quenched sparking”, “ticker”, “tone wheel”, high frequency and rotating field alternators, forms of discharges and mercury breaks, frequency chanter, coils, condensers, regulating methods and devices, etc. This fact would give me supreme satisfaction were it not that the engineers, misinterpreting the nature of the effects, are making installations so defective in construction and mode of operation as to preclude the possibility of the great realization which might be brought within easy reach by proper application of the underlying principles and one of which— the most desirable at present—is the complete elimination of all static and other interference.

During the past few years several emphatic announcements have been made that a perfect solution of this problem had been discovered, but it was manifest from a casual perusal of these publications that the experts were ignoring certain truths of vital bearing on the question, and so long as this was the case no such claim could be substantiated. I achieved early success by keeping thee steadily in mind and applying my efforts from the outset in the right and correct scientific direction. I may contribute to the clearness of the subject in answering a question which I have been asked by the Editors of the ELECTRICAL EXPERIMENTER with reference to the report contained in the last issue, that signals had been received around the globe, an achievement the practicability of which I have fully demonstrated by experiment eighteen years ago.

The question is, how can the Hertz waves be conveyed to a distance in view of the curvature of the earth? A few words will be sufficient to show the absurdity of the prevailing opinion propounded in text books.

We are living on a conducting globe surrounded by a thin layer of insulating air, above which is a rarefied and conducting atmosphere. If the earth is represented by a sphere of 1294 miles radius, then the layer which may be considered insulating for high frequency currents of great tension is less than 1/64 of an inch thick. It is held that the Hertz waves, emanating from a transmitter, get to the distant receiver by successive reflections. The utter impossibility of this will be evident when it is shown by a simple calculation that the amount of

(Continued on page 628)
GERMANS USE BICYCLE DYNAMO TO OPERATE RADIO SET.

The accompanying illustration shows an ingenious German method of generating the necessary electric current for operating a radio installation in the trenches, which was captured in a recent British advance. As the photograph shows, a tandem bicycle with its wheels removed has been fitted with a supporting frame so as to stand upright and the pedal wheels connect with a belt to a small dynamo.

Such an outfit will produce considerable electricity which can be used for radio or lighting purposes, etc. In fact, this scheme is not new to the American wireless amateur, for we published an article on such a device for producing current to operate a wireless transmitter several years ago. A person sitting on a bicycle fitted with proper gearing, exhibits a great deal more power than would be imagined off hand, and besides for warfare requirements the outfit is noiseless, albeit it is not quite so handy as the small gasoline engine outfits used by some of the other armies.

NEW TELESCOPING RADIO TOWER.

A device that promises to be of great importance to the field wireless service is a telescoping tower that can be raised almost instantly on the throwing of a lever. This tower, the invention of R. W. Dean, of Des Plaines, Illinois, has been presented to the Government.

The tower that carries the wireless aerial works on an extremely simple principle. A number of light steel pipes fit inside of another, the space between them being made air-tight by a series of washers at the top of each but the middle pipe. The base-pipe connects with a comprest-air reservoir which is always kept filled by an air-pump.

The operators turn on the comprest air lever. Air from the tank rushes to the top of the innermost pipe and pushes up on it with a force upward of twenty-five pounds for every square inch of its surface. The sections shoot upward, one after another.

Of the 8,000 girls who applied for service as military telephone operators with the American forces, abroad 650 were accepted.

Marconi Company Claims Famous "Static Preventer" Discovery

"With the conditions that pledged us to absolute secrecy no longer prevailing, the Marconi Wireless Telegraph Company of America is permitted to announce a discovery and invention in wireless telegraphy which will mark a new era in world communication," says a statement issued by Edward J. Nally, Vice-President and General Manager of the Marconi Wireless Telegraph Company of America.

"Ever since the genius of Marconi made wireless telegraphy a fact, the only limitation of this method of communication was the deadly phenomena of 'static conditions.'

"It remained for an American radio expert, Roy A. Weagant, Chief Engineer of the Marconi Wireless Telegraph Company of America, to discover the solution of the static problem.

"Among the revolutionary changes that the new system effected in wireless installations will be the immediate disappearance of the huge steel towers, heretofore built at great heights to catch the incoming wireless waves. Equip with the Weagant invention, the wireless receiving antennae are stretched merely a few feet above the ground.

"Herefore, also, the increasing number of high power stations that were being erected in every part of the world raised the difficult question of 'interference.' Crossing wireless messages that shot thru the ether sometimes made the wireless signals so indistinct that they could not be understood, or drowned the weaker transmission entirely. The Weagant system, based on a unique selective principle, eliminates 'interference' and permits absolutely clear communication, regardless of the operation of other stations even in the immediate vicinity.

"The notable contribution to wireless telegraphy opened by Mr. Weagant's discovery makes continuous wireless communication over the oceans and between continents an absolutely assured fact for twenty-four hours of the day and every season of the year, regardless of atmospheric conditions. All the Marconi high power stations are being equipped with the Weagant system, and the stations of the Pan-American Wireless Telegraph and Telephone Company, which are to link North and South America, will likewise be equipped.

"This invention sounds almost too good to be true. However, Mr. Weagant, in an interview with the ELECTRICAL EXPERIMENTER's representative, stated that by very careful study of the subject over a considerable period, discovery of an entirely new principle had been made, and by accident at that. It was, as expected, but while making investigations along other lines this particular effect became more and more noticeable until it developed into a full-fledged invention. "As soon as official 'Peace' is declared," said Mr. Weagant, "I will present a technical paper before the Institute of Radio Engineers describing the invention. Also a body of technical men will be invited to one of our stations to hear it work."

SHIPS PERMITTED TO USE RADIO AGAIN.

Announcement has been made by the Naval Communication Service that commercial wireless traffic between United States merchant vessels and naval radio shore stations would be resumed at once. This means that wireless messages may be sent to passengers on board steamships and that travelers at sea may communicate with shore.

During the war steamships were forbidden to use their wireless except to listen, the precaution being taken to prevent submarines and surface raiders from learning the positions of Allied vessels.

OCTOBER MEETING OF INSTITUTE OF RADIO ENGINEERS.

The Institute of Radio Engineers held a meeting on the evening of Wednesday, October 9, 1918, in the Engineering Societies Building, New York City.

A paper on "SPECIAL HEATING EFFECTS OF RADIO FREQUENCY CURRENTS" by PROP. EDWIN F. NORTHUP of Princeton University was given.
Squadrons of American airplanes fighting in France up to the moment of the armistice, were maneuvering under the vocal orders of the squadron commander that reached each pilot by radiotelephone.

News of the successful development of this device, hitherto a military secret, tho some inkling of it had reached the Germans just before hostilities ceased, was made public recently by John R. Ryan, Director of Aircraft Production.

There are some details concerning it which we cannot discuss yet," Mr. Ryan said, "but the radio devices worked out during months of experiment went into actual service some weeks ago. I have myself, standing on the ground, given orders to a squadron flying in the air and watched them maneuver accordingly.

"The transmission of the voice is clear enough to be heard distinctly thru the sound of the airplane motor. It is in every way the most satisfactory means of communicating between planes in the air and from the ground to planes."

The distance over which the radiotelephone talks from earth to plane is a matter of several miles.

"For some months," said William C. Potter, of the Equipment Division of the Bureau, "it has been possible in our offices in Washington to hear the planes flying miles over the city, talking to each other and to the ground as they worked out and perfected the device."

The accompanying views show several of the radiotelephone apparatus which can also be used for wireless telegraphic transmission when desired and utilizing the De Forest Oscillon bulb having a filament, grid and wing. The oscillon comprises an exhausted glass tube or bulb, the size of which depends upon the output in watts, and which greatly resembles an ordinary incandescent lamp. This bulb contains two additional elements besides the usual incandescent filament, which are known as the plate and grid respectively. In these oscillons, the grid consists of a spiral winding of very fine tungsten or other wire wound upon a glass frame, and so placed as to entirely surround but not touch the filament. The plates, of which there are two, are placed one on each side of the filament, outside of, but not in contact with, the grid. In operation, the oscillon or vacuum bulb, oscillation generator requires two sources of potential, one of low voltage for lighting the filament, and one of high potential for supplying current from plate to filament across the vacuous space within the tube.

A small motor-generator suitably wound to supply the proper voltage is generally employed as the most convenient source of current. Reception of radio-telephonic or telegraphic waves is accomplished by the use of a similar but smaller sized vacuum bulb, which is capable of generating oscillations by a re-action between two or more tuned circuits, so that either damped or undamped oscillations can be interpreted.

Fig. 1 of the accompanying views shows a complete airplane Radiophone oscillation transmitter, especially designed for military use. In this set the weight has been reduced to a minimum. A special "chopper" or calling key is fitted to the instrument as well as a special type of microphone for modulating the oscillations in the form of speech waves. At the left of the photograph will be observed a small dynamo resembling an airplane bomb, one end of which is fitted with a small size propeller. This dynamo is driven by the force of the air turning the propeller, as the airplane speeds along, and thus current is produced for the operation of the oscillon. The large oscillon bulb is enclosed in a wire cage to protect it from breakage, and the necessary measuring instruments are mounted on the front of the panel, viz: a hot wire ammeter in series with the antenna circuit to measure the radiation current, a milli-ammeter indicating the "B" battery current, and a filament battery ammeter. Suitable tuning inductances and capacity control knobs are mounted on the front of the panel. The connections between the various parts of the apparatus are accomplished with flexible twin conductors sewn in leather straps, the ends of which are provided with separable jack plugs.

The illustration in Fig. 2 shows a combination audion, ultra-audion and one-step amplifier. This combination is similar to the audion two-step amplifier outfit, with the exception that the apparatus is arranged for one-step amplification. This set will meet conditions perfectly, it is claimed, where the intensity of the normal signals does not.
The Manufacture of Vacuum Detectors

By O. B. MOOREHEAD

ALTHO the majority of radio engineers are familiar with the use and operation of vacuum tube detectors, a brief description of their manufacture may be interesting. In the early experimental work on this type of device, we strove to produce a detector by combining maximum operating power with inexpensive manufacture. The next point considered was that of desirable conditions, i.e., tubes that possessed oscillating characteristics, tubes that were exceptional detectors, and tubes that displayed both qualities, says O. B. Moorehead, in a paper recently presented before the Institute of Radio Engineers. The third consideration was the production of a device easily handled and assembled, without disturbing the adjustment of the elements and damaging the filament.

Tubes and bulbs of various shapes and sizes were tried, using a gaseous medium ranging from one millimeter to 0.025 millimeter of vacuum, many materials being employed as elements. Various exhausts were applied, but it was soon found that the employment of a gaseous medium introduced considerable difficulty in the matter of accurate reproduction of a desired result. Gases at pressures ranging from one millimeter to one-fifth of a millimeter were next experimented with.

I found that a tube containing a platinum filament in an atmosphere of hydrogen, at pressures comparable with one millimeter, gave fair results. Tungsten filaments were then tried in higher vacuas as well as at the so-called "gaseous medium" pressure. It was immediately noticed that conditions could be duplicated as soon as a vacuum above that which allowed a "gaseous medium" pressure was obtained. Moreover, tungsten was ideal as a filament not only because of its refractory qualities and low volatility but also because it acts as a purifying agent by dissolving any traces of residual gases that may remain in the tube and forming compounds which are then volatilized on the walls of the tube.

As the parts are small and complicated, the glass is worked before the blowpipe, after it has been brought into the form of tubes, and the blowpipe is then cleaned. The tubing is obtained by first blowing a bulb, then fusing an iron rod to a point diametrically opposite the blowpipe and rapidly separating the two points of attachment from each other. Various grades of glass were experimented with, and a mixture containing a high percentage of lead and a small quantity of siliconic acid was found to be the easiest to work and produced a detector of maximum sensitiveness when used in conjunction with the aluminum plate and copper grid. In the selection of the glass to be used, the devitrification of the glass had to be considered, as during exhaustion of the glass it is necessary to subject them to heat at temperatures near the point of softening and nearly all glasses, when maintained at this temperature for any length of time, have a tendency to separate out into the crystalline state.

There has been considerable discussion regarding the elements in this type of device and I may say that aluminum plates and copper grids were first selected on account of their electro-chemical relation to the tungsten filament. Later, numerous other metals were tried under the same and other conditions of exhaustion and showed widely different operating characteristics.

The selection of metals for the elements is very difficult, as a slight difference in either the copper or aluminum changes the whole system of exhaustion. For instance, copper and aluminum purchased from one factory lot will require a certain degree of applied temperature during the evacuation, while another factory lot of the same weight and size will require an entirely different exhaust.

I have eliminated this variation to some extent by subjecting the aluminum plates to a temperature of approximately 600 degrees Fahrenheit (315° C.), immersing them in a saturated solution of cyanide of potassium, and finally rinsing in alcohol. The copper is subjected to heat until it glows, while it combines with the oxygen of the air to form a black, brittle oxide which breaks off in scale and exposes the underlying metal which is of rose red color. It is then placed in a current of moist air and becomes covered with a layer of oxygen compounds, which remains very thin but heated to high temperatures.

The lead glass tubing, used as the container for the elements in the tubular type detector, is obtained from the manifolds in lengths of 6 feet (2 m.) with an inside diameter of 0.087 inch (2.2 cm.) and a wall of 0.003 inch (0.7 mm.), and one end is cut in lengths of about 6 inches (15 cm.) and one end is drawn down to a point. Two stems are made of glass tubing similar to those used in an incandescent lamp, one stem contains the grid and two filament leads, and the other contains the plate connection and the filament lead. After the wires are sealed into these stems, they must be annealed very carefully. The annealing consists in allowing the temperature to drop very slowly, since quickly cooled glass is subject to internal strains which arise in the following manner: In rapid cooling, a low temperature is soon established at the surface and the glass works layer solidifies while the interior tends to contract, thereby exerting a pressure on the outer layer which is directed inward. This may cause the stem to crack.

After the stems are annealed, the grid is wound to the proper diameter and the filament is clamped onto the plate by means of a device. The plate is mounted on the other stem and the two stems are then connected together by means of the filament. Final adjustment of the plate and grid spacing so the spacing between the elements is not very critical in this type of device, but it is best to wind the grid to a thickness such that it will strike the plate rather (Continued on page 671)
A Vertical Cabinet Type Coupler
By JOSEPH H. KRAUS, Jr.

CABINET couplers, altho handsome and efficient, are quite expensive, even if the amateur attempts to make one himself. In the following article is given a description of a large cabinet coupler which did remark-

able work and the cost was surprisingly low. An instrument such as this is an asset to any station and will well repay the ambitious Radio Amateur for the time and trouble involved.

THE PRIMARY (WINDING WITHOUT A LATHE)

Two cardboard tubes are first procured, eleven inches long by five and four and one-half inches in diameter, respectively.

The five inch diameter tube is first wound in the following manner: In the center of a rod of wood about two feet long and of a diameter that will easily pass into both the five and four and one-half inch tubes (a broomstick handle will do) drive several nails, in such a manner that their heads protrude about one-half inch from the wood. This wooden rod is then placed in the five inch primary tube and held as near to the central axis as possible while cotton waste is packed in around the axle. The friction of the cotton waste against the tube will prevent it from slipping when it is being wound and the nails will act as grips for the axle (Fig. 1). A crank is now fastened to one end of the axle and the whole is suspended from two "Y" shaped uprights nailed to the opposite ends of a small box (Fig. 2). By using this cotton-waste method there is no necessity of fitting a rod tightly into the tube and a lathe is not essential. The winding is now commenced three-fourths of an inch from one end of the tube and a tap eight inches long is taken off every turn for the first twenty turns. Number these starting with the first wire as No. 20, then 19, 18, 17 and so on down until we get No. 1, and then No. 0. These taps must not be taken off directly under each other, but they zig-zag or spiral one-third around the tube, so as not to allow the least chance for a short circuit between two turns. Each must be carefully insulated and No. 22 black enamel wire used.

The manner in which a tap is taken off doesn't make much difference and every Amateur has a method of his own. However, here are two "standard" methods. For the primary the preferred method is to solder a wire to the place where the tap is taken off and insulate it carefully. Another method is to twist a loop into the wire and then continue winding; this will constitute a double wire lead (see Fig. 3). (This method will save trouble in the secondary winding.)

After the twentieth tap has been taken off (No. 0) the wire is wound for twenty turns and then a tap taken off. In this way the tube is wound until one-half inch off every three-quarters of an inch of winding. These loops are made one inch long and are taken off spirally one-third way around the tube. As the winding proceeds and as each tap is taken off a hole is punched into the cardboard tube immediately under each tap and a match stick inserted into the opening; each respective tap is to be drawn thru its particular opening. When complete there should be fifteen taps. Now to each of these is soldered a piece of flexible cotton or silk covered wire about twenty inches long, a piece of rubber tubing slips over the joint and the wire drawn thru the center of the coil toward one end thru its respective opening. Number each tap in order, shellac and allow to dry.

Note: These wires are not soldered on until the tube has been fully wound and removed from the crank.

(Continued on page 671)
NEW "BUMBLE-BEE" HY-TONE CODE PRACTICE SET!

Here's the hy-tone code teaching outfit you have been looking for, Radiobugs!

[Diagram of a hy-tone code practice set]

The set works as follows: The sending key (A) closes the circuit thru the battery (B) and lamp (C). The light works the selenium cell (D), operating the relay (E), which closes the circuit of the specially quick-starting and stopping motor (M). A fan (F) on the shaft of this motor plays a breeze on the plant (I), waiting an Aroma de hyacinth to the unsuspecting bumble-bee (I), which is tuned to a clear hy-tone. The microphone picks up the bumble-bee's buzzes faithfully and reproduces them in the telephone receivers. Every time you press the key it buzzes. Voila!

WIRELESS MESSAGES REACH ARCADIA CAL. FROM BROOKLYN YARD.

The wireless station at Arcadia, Cal., by using for an aerial the cable of a balloon, put aloft from the training field, has intercepted messages sent by the Brooklyn navy Yard wireless station, according to an announcement by the War Department. This balloon cable probably makes the highest aerial in the world.

This announcement was made by the Division of Military Aeronautics, indicating increasing efficiency in both the work of students and the equipment of the War Department's various balloon training fields.

The balloon school at Arcadia has 106 miles of wire in use for teaching military communication. For the purpose of demonstration it has a complete system of wiring, running as it would be in the front line trenches on the battlefield. Communication posts and stations for all kinds of messages are used by the students in the same as soldiers use them at the front.

A good part of the country southeast and southwest of Arcadia is laid out with lines of communication to this balloon school, similar to part of a sector at the front. All of the balloons, when aloft, are so wired that they can be lined together with any trench, doubled up for any work together, or they can be cut off from the trenches and talk only with their own chart room and winch or operating crew on the ground below.

It is reported that the U.S. Government purchased the Sayville, L.I., Radio Station shortly after the declaration of war.

SPAIN TO AMERICA BY AIR IS PROJECT IN MADRID

Captain Herrera, chief of the hundred Spanish military air forces, has had a number of interviews with King Alphonso on the subject of aerial postal and passenger service between Spain and the United States. The scheme also has been discussed at Cabinet meetings and it is said that a leading shipping company is willing to finance it.

The plan, it is understood, is to manufacture large airships capable of carrying forty passengers, besides the mail. The rate charged for a passenger, if the scheme is carried out will be $200, and letters will be charged for at the rate of $1 the 0.003 uf. line, weight (about three ounces and a half). It is estimated the journey would take two and a half days.

A BATTERY-LESS TELEGRAPH.

A simple telegraph set may be put up between two chums' houses by running a small wire from house to house about 20 feet above the ground and 50 feet from the lighting wires in the street; connecting a key and receiver as shown in the following diagram. No batteries will be needed. One wire is grounded to the gas or water pipe. It works by induction from the lighting circuit.

Contributed by RAY L. MILLER.

A Batteryless Telegraph System. It Operates by Induction in a Regularity A. C. Lighting Circuit.

Where so lighting line is in the neighborhood, bury a zinc plate in moist earth at G, and a copper plate at G'. This system was once used by the editor, and by using a 75 ohm receiver at each station, satisfactory results were had over 1/2 mile. This "ground battery" gives about .07 volts.

AN ENT THAT RADIO COMPUTATION GRAPH.

WTH regard to the article in your September issue, "A Graph for Solving Wave Length, Frequency, Inductance and Capacity," I would like to point out that all the commercial values of the quantities can be expressed by the graphs. Of the published diagram bounded by the lines representing one milli-henrey, 01 milli-henrey, 0.1 uf. and 10^-6 uf. (uf. = microfarad.) To do this two inductance scales are required as in the diagram herewith.

Each diagonal line represents two wave lengths, one being ten times the other, as shown for 600,6000, and 2000,20,000,000; giving directly a range of 600 to 20,000 meters, the left-hand inductance scale being used for the lower range of wave length, the right-hand for the upper range.

Only a part of the commercial waves below 600 m. are obtainable directly, but values not on the chart can easily be determined as follows: To find, say, the inductance required for 300 m. with 0.003 uf., note that the 0.003 uf. line intersects the 3,000 m. line at 0.000084 h. Divided by 100 we obtain 0.0000084 h., the required value. In general, using the line representing 10 times the wave length, divide the required value by the graph by 10 and vice versa. Values of inductance and capacity not shown directly may be determined as follows: Suppose we wish to find the 0.0001 uf. required with a wave of 8,000 m. and capacity of 1.7 uf., which are approximate values of the Glace Bay transmitter primary; divide the capacity by 1,000. The line for 1.7x10^-3 intersects the 8,000 m. line at about 1.06x10^-5 h. Dividing by the same number by which we divided the capacity (1,000) we obtain 1.06x10^-8 h., the required value.

The procedure would be exactly similar with a known inductance and wave length. By extension of the above procedure, which is simply based on the fact that wave length varies as the square of the capacity or of the inductance, as the case may be, and that the product of capacity and inductance is constant for any particular wave length, we can obtain any wave length, inductance and capacity, but if many values are required which are not on the chart, it would be better to construct another pair of squares of the original graph from which the values could be read off directly. The advantage of this graph over the original one is its increased scale, which is ten times that of the original one for the same size paper. It is also easier to construct the number of logarithmic lines required being but 5/17 of the number required for the original.
Building a 3-Inch Spark Static Machine

By DR. E. BADE

Friction is one of the commonest sources of static electrical excitation. Every one has noticed how the hair crackles under the comb in dry weather. The same sound is heard on stroking the back of a cat, and, if the room is dark, sparks may be drawn from pussy's fur. But for developing large quantities of electricity by friction a static machine is utilized. The simplest form of such a static machine which will develop sufficient electricity for all kinds of devices, as it gives a spark ranging from one to three inches in length, according to the neatness and exactness of the finished apparatus, altho one of excellent construction will give a larger spark, consists of a revolvable glass plate, a rubber and a conductor. The capacity of the conductor can be heightened with a well insulated iron ring capable of being attached or taken off from the conductor at will.

The wooden frame is to be made first. It is constructed from hard dry wood (walnut or mahogany); the base is 20 inches long, 12 inches wide, and 2 inches thick; the edges are beveled off. The two supporting arms can be made from thinner wood, but each should be 15 inches long, 4½ inches wide at the bottom, and 3 inches wide at the top. These arms, which are dovetailed to the base, are fastened with two screws countersunk; the holes being later plugged

rod one foot long and a half to ¾ of an inch in diameter is taken for an axle. Two small wooden rings serve to hold the cemented plate to the rod. One should be careful to see that the axle is perfectly horizontal and the plate exactly perpendicular. One end receives a handle and a wooden ring which prevent it from slipping from the supports.

Now a "rubber" is made from three pieces of wood. The lower part is made from a piece 5/8 inches wide and 4 inches long. The sides, which are made to slant slightly upward, are 4⅜ inches high. This frame is supported by a glass rod 4 inches long which is sunk into the wood. The other end is placed in a fork 4 inches long, 2 inches wide, and ¾ inch thick. With the aid of this fork the frame is fastened to the base board by winged screws. But before this is done a small brass knob or ball is attached to the frame which in turn is attached, by means of tinfoil, to the rubbers.

Each of the two rubbers consist of a board on which soft, thick felt is glued. A spring presses the rubbers lightly against the glass plate. In order to prevent the rubbers from falling out a short piece of wood is nailed to them so that it projects and catches against the frame. Each rubber is now covered with an amalgam consisting of two parts of mercury, one part of tin, and one part of zinc. This must be evenly distributed over the surface with the finger. If this will not adhere a little lard (fat) may be used.

The conductor with the metal comb is made next. The former consists of a four or five inch hollow brass ball fastened to a glass support. The ball receives two holes thru which a brass rod is placed carrying the comb. The top of the ball also receives a hole which will later carry the ring as well as other pieces of apparatus for experiments. The metal points of the comb are attached to two rings of tin, each of which is fastened to a wooden ring. The metal rings are each 3 inches in diameter.

The points consist of ordinary thumb tacks. When the rings are placed between the glass plate, the points should be at least ½ of an inch from the glass. Under no circumstances should they touch the plate.

A flap of silk is glued to the rubber which (Continued on page 673)
How I Built a Model Gyro-Electric Destroyer

By LeROY H. MAHONY

The illustration represents a 25-inch model of Mr. Gernsback’s “Gyro-Electric Destroyer.” The entire machine with the exception of the Gyroscope and the driving motors was built of “Meccano” parts.

I next turned my attention to the main axle and the gyroscope. The gyroscope I turned from two pieces of ¾ inch wood 8 inches in diameter. To the side of it I secured a small sprocket for the driving chain. The gyroscope must run FREE of the large quantity of silex in the substance require the tools to be extremely hard and even then they are subject to rapid wear. It also contains an oil which prevents nails driven into it from rusting.

EinTHOven GALV. STRING.

A commercial form of Einthoven galvanometer string is shown below. The case, F, contains the fine wire carrying the current to be measured. The figure shows schematically the detailed construction of the suspension for the fine wire E, which must be as fine as possible. Platinum, silver or aluminum can be used, but it was found that even a smaller diameter can be obtained by using quartz or glass fibers, these being platinized or silvered. The ends of the wire are soldered to T-shaped members, which are held by the set screws C and F at the ends. Adjusting the tension of the wire is a close operation and it is carried out by mounting the upper wire carrier upon a rod having the cam K at the upper end, the rod being normally pushed up by a spring L. The lever K’, presses the rod down, this lever being operated by the micrometred screw J. With this arrangement a very fine adjustment of the wire is secured.

Contributed by SAMUEL COHEN.

I first constructed each side of the big wheel. To a bush wheel I bolted eight 1½-inch strips equally divided into angles of 45 degrees. I then bolted together seven 1¾-inch strips overlapping two holes each. I bent this around the ends of the side braces and fastened it to them by means of angle brackets. In the same way I constructed the other side. I selected pairs of ½-inch strips and bolted each pair together, overlapping them one hole. Three center treads, the same in circumference as the sides, were then made of seven more 1½-inch strips, overlapping two holes. It now remained to connect the two sides and the center tread together by means of the preconstructed pairs of ¾-inch strips. One pair was bolted at right angles to each side brace and one equally placed between them. To preserve more stability, I connected the side braces with 3½-inch strips. This completed the main wheel.

The next part to consider was the engine cage. Three small plates fastened side by side with ¾-inch strips, composes each side, while each end comprises a large plate with the flanged edges flattened out. The sides and ends were fastened together by angle brackets. It is necessary to fasten inside the cage two motors (preferably electric), one to drive the gyroscope separately, and the other to propel the entire machine. As to the position in the cage for these motors—that is left to the discretion of the builder as his type and size of motors may differ from those of the writer. However, the motor driving the gyroscope must be placed in the center as the gyroscope must be driven in the center. The other motor must turn the axle of the wheel by means of chain and sprocket. On each side of the cage is fastened a ¾-inch strip so that the cage is suspended from the center axle.

Teak the Hardest of All Timbers.

People familiar with different kinds of wood are aware that African teak is the hardest timber known to the mechanical industries. So indestructible is this teak wood that vessels built of it have lasted over one hundred years. The peculiarity of this wood is its hardness and great weight, causing extraordinary durability. Its weight varies from 42 to 52 pounds per cubic foot. It works easily considering its hardness, but

The who are interested In building an Einthoven string galvanometer for measuring and recording radio signals, as described in the September and October issues, will find to the detail of the string suspension of value.

Here is a Fine Model of the “Gyro-Electric Destroyer.” It is Fitted with Electric Motors and All. It was Constructed by the Author from “Meccano” parts. It Stands 25 Inches High and Weighs 15 Pounds.

Fig. 2
A Simple Study of Currents and Magnets

By Prof. E. H. JOHNSON, Dept. Physics, Kenyon College

(Conclusion)

If now the wires J and K are joined to a direct current circuit of several volts, the wire, H, will rotate about the iron rod, D, which is now a magnet, and it will be found that the direction of this motion will depend on the direction of the current in the wires. It may take a little study to see how the action is in accordance with the principles previously defined, but it will be found to be no exception to the rule.

In this case the only difficulty will be to get it accurately balanced. It should have 10 or 12 spokes, which may be soldered to a heavier copper wire for a shaft to be laid across the finished ends of the supporting wires from the post, A. When the balancing is fair the wheel should turn as easily in one direction as the other, or remain stationary. To do this the mercury pool, with which the ends of the spokes make contact, is connected as before, by a wire to one end of the coils of the magnet, and their other end is joined to the other binding post, B, so that a current may pass thru the apparatus between A and B. In this case the effect will be continuous with the proper current, and we have a fair type of electromagnetic motor. Again, our right-hand rule should be applied, considering the current as flowing up or down, as the case may be, in the spoke touching the mercury, to see if the rotation is what should be expected.

Other experimental devices such as these will readily suggest themselves to the experimenter, and he should learn to look at all such arrangements with that keen appreciation which sees not only the wires and mechanism, but which recognizes at once the underlying principle of its operation. When this habit has been formed and some of the information which it will inevitably bring, has been acquired, the entire field of electromagnetism, including dynamo-electric machinery in all of its phases, will open up with a surprising simplicity and consequently with endless interest.

ELECTRIC FLASH-LIGHT IGNITER.

Having some difficulty when taking flash-light pictures with cartridges, with the fuse not igniting the powder, or putting the subject on guard, frequently catching him with his eyes closed, and being badly burnt by the powder once, I constructed the apparatus shown in the accompanying sketch. It will run nicely on four dry cells. The principle is that when the batteries are short-circuited, the wire gets red hot.

The wires leading from the powder box are the kind known as bell or annunciator wire. Inside the box, the wire wound between the tacks is about No. 40 gage. When the box is constructed, place some powder in the box, press the push button, and off goes the powder. To make the apparatus portable, put the batteries in a box, and mount the powder box on top of this. In this way the operator may appear in the picture himself, if the wires are concealed behind furniture and his person. This also catches the subject off his guard, giving him a natural pose; it enables the operator to be at a safe distance from the powder. If a spark coil is procurable, it can be used instead of batteries by running a pin thru each side of the box making a spark gap, connecting the wires to a handle and pressing the button. I have used this apparatus extensively and successfully myself.

A "BATTERY-LESS" MAGNETO DOOR BELL.

A small magneto generator is placed in a box (properly stained and finished) on the back of the door. A turn of the knob rings the bell, which may be an ordinary vibrating bell. Best results are obtained by winding it to from 100 to 300 ohms. An old crank escutcheon plate from a magneto telephone may be placed on the front of the door. This device when properly made is neat in appearance and does away with all battery troubles.

Experiments in Radio-Activity

By IVAN CRAWFORD

PART 1—Ionization

Radio-activity is one of the greatest mysteries of today. The modern scientists, however, thru experiments have succeeded in throwing considerable light upon the subject. The term radio-active is generally employed in referring to such elements as uranium, thorium, radium and their compounds which possess the property of emitting radiations capable of penetrating many substances opaque to ordinary light. These radiations also have the power of affecting photographic plates, ionizing the gas thru which they pass and causing fluorescence on certain substances placed in their vicinity. It is deemed unnecessary to enter further into the explanation of radio-activity as it has been well described by Mr. Jerome Marcus in previous issues of this magazine. It is the purpose of this series of articles to merely outline some experiments on this extremely interesting subject.

The most important property possessed by the radiations of radio-active substances is the power of discharging electrified bodies. Hence, the discharge of an electroscope placed in the vicinity of the radio-active substance, furnishes an efficient means of measuring the intensity of the activity.

The construction of a super-sensitive electroscope suitable for these measurements is clearly depicted in Fig. 1. The metal shell consists of a large oil can with the bottom and spout removed. Two round holes are cut opposite each other about half-way up the side. As is clearly shown in the drawing the gold leaf is fastened to a brass strip which in turn is suspended from a sulfur lead. In to the other side of this lead is fastened a wire which passes thru the sulfur block at the top of the chamber. Another wire is then past thru the block and bent as shown. The sulfur block is made by pouring melted sulfur into the opening and allowing it to harden. In order to charge the electroscope the belt with a, is turned so that the lower portion makes a contact with the brass strip. A charged rod is then applied to the other end, b, until the desired charge is attained, when the wire may be turned back and back with the rod. The gold leaf is attached to the brass strip in units of a small drop of some adhesive. In order to observe the discharge, a small low power microscope having a scale on the eyepiece is used. This is mounted in one of the apertures by fastening a brass tube to the shell of sufficient size to allow the microscope to be easily adjusted. A similar brass tube with a ground glass window is mounted in the opposite aperture. This is to facilitate the illumination of the chamber. Using this instrument the rate of discharge may be accurately measured by noting the fall of the gold leaf on the scale. The substance to be measured is placed on a grounded plate and the electroscope placed over it. The radiations by means of their ionizing properties cause the charge of the gold leaf to be dissipated. In Fig. 2 is shown a photograph of such an instrument which was constructed by the author. Some very accurate measurements have been made using this instrument.

To determine the activity of an unknown substance the electroscope should first be charged until the gold leaf coincides with one of the markings on the scale. The time required for the leaf to pass over five divisions on the scale should then be noted with the electroscope empty. The reciprocal of this time is then the measure of the discharging current. The electroscope is then recharged to the same point and placed over the substance to be measured. The time required for the leaf to pass over the same five spaces is again noted. The difference between the reciprocals of these two time elements is then the measure of the discharging current due to the presence of ions produced by the radiations from the substance. It may be shown that the discharging current I, which is proportional to the radio-activity is proportional to \( I = \frac{1}{t} \) where \( t \) is the time of discharge in the presence of the substance, and \( I \) is the time when empty. Thus by comparing times the radio-activity of equal masses of various substances can be measured. Uranium oxide is taken as a unity and uranium nitrate, thorium nitrate and uanyl chloride were compared with this. The results are shown in the following table:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Formula</th>
<th>Time (sec)</th>
<th>Relative radio-activity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uranium oxide</td>
<td>( \text{UO}_2 )</td>
<td>1.00</td>
<td>1.00</td>
</tr>
<tr>
<td>Uranium nitrate...</td>
<td>( \text{UO}_2(\text{NO}_3)\cdot 6\text{H}_2\text{O} )</td>
<td>0.25</td>
<td>0.25</td>
</tr>
<tr>
<td>Uranium chloride...</td>
<td>( \text{UO}_2(\text{NO}_3)\cdot 4\text{H}_2\text{O} )</td>
<td>0.45</td>
<td>0.45</td>
</tr>
<tr>
<td>Thorium nitrate...</td>
<td>( \text{ThO}_2(\text{NO}_3)\cdot 12\text{H}_2\text{O} )</td>
<td>0.38</td>
<td>0.38</td>
</tr>
</tbody>
</table>

It will readily be seen that the activity of a substance is proportional to the amount of uranium or thorium it contains. There are other considerations, however, which affect the experimental results, such as the state of the substance, whether powdered or in lumps. Every electroscope also is different, and all quantitative experiments should be conducted using the same instrument.

It will be found that the distance between the substance and the gold leaf affects the rate of discharge. For uranium compounds the most effective distance is about 3 cm., while for thorium compounds it is about 5 cm. Ionization by radio-active rays is by no means uniform along the path of the rays. In Fig. 3 is shown the ionization caused by a sheaf of parallel rays as determined by Geiger. The range is laid out horizontally in cm., the number of ions are laid out vertically. It will be seen from this graph that when the alpha-rays pass thru ordinary gases to lose some of its enormous speed it becomes a more effective ionizer; near the end of its path, however, its power suddenly decreases.

The experimenter will find innumerable other applications for this electroscope to

(Continued on page 672)
REMOTE CONTROL SWITCH FOR LIGHTING CIRCUITS.

After obtaining the necessary material listed below, remove the handle from the knife switch, and substitute a weight made from 2" length of conduit pipe and \( \frac{1}{4} \)" x 2\( \frac{1}{4} \)" stove bolt. The head of stove bolt is filed flat on one side so as to be properly engaged by the trip arm. The bolt is placed in one side of pipe, and pipe filled with melted lead and allowed to cool off. The threaded end of bolt is then inserted thru hole (in insulating bar across knife switch) formerly occupied by screw holding handle. If properly placed this weight does not come in contact with either of the switch blades.

Now place the fuse block in upper left-hand corner of the iron box as shown on sketch, then place knife switch in bottom, the one side of base being against back of iron box and the whole switch so mounted as to allow weight to swing down and close switch without hitting side of box. The rubber bumper is then placed on bottom of box either with small stove-bolt counter-sunk in the rubber or with a small wood screw from the under side.

The object of the bumper is to prevent the weight from snapping off the insulating cross piece of switch when switch drops.

The casting on base for holding gong should be obtained with a hack-saw just beyond the screw hole, and the ball hammer can be cut off with a pair of cutting pliers, leaving the hammer arm intact.

In placing the bell it will probably be necessary to build it out from the back of the box over two holes, so as to have weight on switch. This building out should be done with either a piece of fibre, porcelain or iron washers. No wood or combustible material should be used. Bend trip arm as shown in sketch, so as to engage the filed side of stove-bolt-head which protrudes thru the weight.

All mountings should be made with stove-bolts, drilling holes in iron box where necessary. If box is thick enough to allow threading machine screws may be used.

The rubber bushing to protect bell wires can be inserted in the box at any convenient place and a narrow piece of linen tape or wire twisted tightly around the inside will serve to hold it intact.

Place the attachment plug on one end of the lamp cord, knock out one of the punch run and the button and place the B. X. connector, insert the cord thru this and wind the cord with tape on the inner side of the connector so that the clamping device can be tightened thereby holding lamp cord, preventing pull on the connections at fuse block and at the same time serving as a bushing for the cord. Connect other end of cord to fuse block as shown.

Make all connections as shown using the No. 14 wire for the lighting circuit and ordinary bell wire for battery circuit.

Only one blade of the knife switch carries current for the ordinary two-wire lighting circuit. For the three-wire circuit the two blades are used and an additional lamp cord and attachment plug are required.

Installation: This apparatus should be mounted on wall close to house fuse box and not more than 6 or 6\( \frac{1}{4} \) ft. from floor. To connect to an installation one fuse is removed from the house fuse box and the attachment plug inserted in its place, the fuse can then be placed in the "fuse" socket of the apparatus. The bell circuit can easily be run and batteries installed at any convenient point.

Operation: By closing battery circuit, the hammer arm of bell, then close the door. Keep pivoted and contact clips of knife switch lubricated with vaseline. This switch can be used for distant cut-in control or in conjunction with burglar or fire alarm systems, cutting in the lights when alarm conditions, and doing away with the necessity of running heavy lighting wires. Where the law requires it, a ground wire can be attached to the iron box with a short stove-bolt, and the box grounded to the electric conduit system.

The following material is required to make this apparatus:
- One 7" x 8" iron cut-out or switch box
- One two-wire main line plug fuse cut-out block
- Two dry batteries
- One two-pole single-throw knife switch
- One iron box bell
- One rubber bumper
- One 4" B. X. box connector
- One rubber lamp socket bushing
- One attachment
- One liter 1/4" x 2\( \frac{1}{4} \)" stove bolt
- One rubber knob from old door bumper
- One 2\( \frac{1}{4} \)" length of 1" conduit pipe
- Two of double pole lamp switch, No. 14 reinforced flexible lamp cord
- Proper quantity of bell wire

Contributed by E. C. O'DONNELL.
Boring and Drilling.

Sometimes the lathe can be used with success for drilling purposes if the machined hole is of the desired diameter. In the case of the circular saw, a hole of this diameter is required in the disk for the guide of the blade. In drilling a metal stock, the hole is often of a greater diameter than that required in the finished work. In this case, it is advisable to use a hole of this diameter, as well as to drill the hole with a large ball. The tool should be run at a high speed, and the burr at the end of the drill should be removed. If this is done, the hole will be a true circle, and the edge of the work will be smooth. In boring, the hole is often made in a series of small holes, and the edges of these are removed by the burr. In order to make a hole of the desired size, the tool should be run at a low speed, and the burr removed by the burr. If the hole is made in a series of small holes, the edges of these should be removed by the burr. If not, the burr will be removed by the burr, and the edge of the work will be smooth. If the hole is made in a series of large holes, the edges of these should be removed by the burr. If not, the burr will be removed by the burr, and the edge of the work will be smooth. If the hole is made in a series of small holes, the edges of these should be removed by the burr. If not, the burr will be removed by the burr, and the edge of the work will be smooth.

In boring small holes, the drill should be held by the operator, and the burr removed by the burr. If not, the burr will be removed by the burr, and the edge of the work will be smooth. In boring small holes, it is advisable to use a tool of this size, as well as to drill the hole with a large ball. The tool should be run at a high speed, and the burr at the end of the drill should be removed. If this is done, the hole will be a true circle, and the edge of the work will be smooth.

Boring Out a Casting in the Lathe by Means of a Boring Bar "BR."
The Casting is Secured by Bolts "B" to the Saddle "CS."

PHOSPHOROUS: History.

PHOSPHOROUS was discovered by Brandt, an alchemist, in 1669 at Hamburg. He gave it the name Phosphor [light bearer]. Gahn, in 1769, found it to be a constituent of boneash, and about 1775 Scheele first published his method of preparation from this source. Liebig in 1840 used phosphates as a fertilizer for plants, while Romer [about 1833] first applied it to matches, thus revolutionizing the means of obtaining fire and light.

Occurrence.

It never is found in the free state, but chiefly as calcium phosphate \([\text{Ca}_3(\text{PO}_4)_2]\), the principal constituent of bones. This occurs in certain minerals as Apatit \([3\text{Ca}_3(\text{PO}_4)_2]\) and Phosforite \([\text{Ca}_3(\text{PO}_4)_2]\). The latter being also known as Phosphate Rock, being extensively used for fertilizing purposes.

Phosphorous is always found in plant and animal tissues, in the soil, and in sea water.

Preparation and Manufacture.

It is obtained mainly from bones of vertebrate animals, which usually contain from 55 to 60% of calcium phosphate, the hard parts of invertebrates being mostly Calcium Carbonate, \(\text{CaCO}_3\). These bones are first burned or else distilled. In either case the ash is the same, but in the latter the carbon is retained as boneblack, which in the former gives rise to carbon dioxide. The volatile substances driven off are ammonia and other nitrogenous products, such as water, carbon dioxide, etc. The ash, mostly Calcium Phosphate with a little calcium carbonate, is reduced and phosphorous obtained by three steps.

First.—It is treated with Sulfuric Acid, which changes it to a soluble phosphate, \(\text{H}_3\text{Ca}[\text{PO}_4]\). \[
\text{Ca}_3(\text{PO}_4)_2 + 2\text{H}_2\text{SO}_4 = \text{H}_3\text{Ca}[\text{PO}_4] + 2\text{CaSO}_4
\]

It might be expected that the Sulfuric Acid would change the phosphate salt into phosphoric acid, but the Sulfuric acid used is not very strong and the reaction goes but half way, producing an acid salt. It, however, changes the insoluble phosphate to a soluble one and precipitates the Calcium Sulfate, which is then separated by filtration or settling.

Second.—The liquid is next evaporated, and the solid residue from the evaporation is strongly heated, a process which breaks it up into Calcium Metaphosphate \([\text{Ca}_3(\text{PO}_4)_2]\), \[
\text{H}_3\text{Ca}[\text{PO}_4] = \text{Ca}_3(\text{PO}_4)_2 + \text{H}_2\text{O}
\]

Third.—The reducing agent, carbon, is next added and thoroly mixed, and heat is again applied. When two-thirds of the Phosphorous distills over, the remainder again forms Calcium Phosphate.

\[
2\text{Ca}_3(\text{PO}_4)_2 + 10\text{C} = 3\text{Ca}_3(\text{PO}_4). + 10\text{CO} + 4\text{P}
\]

To obtain the whole of the Phosphorous, Silica \([\text{SiO}_2]\) in the form of sand is introduced, and the following reaction takes place:

\[
2\text{Ca}_3(\text{PO}_4)_2 + 25\text{SiO}_2 + 10\text{C} = 2\text{Ca}_3\text{SiO}_5 + 10\text{CO} + 4\text{P}
\]

Great care is taken not to have the hot Phosphorous in contact with air, and retorts are arranged so that the Phosphorous runs into cold water. See Fig. 153. The Phosphorous must be either redistilled or pre-tatt chamosin skinned to get rid of carbon particles, etc. It is then run into small mounds of copper or glass.

The manufacturing process is detrimental to the health of the workmen. Some of the fumes have to be inhaled, and the breath at night is often luminous. The element attacks the teeth and jawbones, especially the lower jaw, which is sometimes entirely eaten away through failure to cleanse the teeth.

The electrical process has practically replaced the old method. In an upright pear-shaped furnace, an intimate mixture of Carbon, phosphite, and flux is heated by means of carbon electrodes in the electric furnace, as shown in Fig. 154. The mixt is fed in thru the hopper \(H\), the carbon electrodes entering at \(G\). The phosphorous vapors pass off above to a condenser, being condensed under water, and the slag is tatt off below at \(C\).

\[
2\text{Ca}_3(\text{PO}_4)_2 + 25\text{SiO}_2 + 10\text{C} = 2\text{Ca}_3\text{SiO}_5 + 10\text{CO} + 4\text{P}
\]

1. It is found in several allotropic forms, the most important being the yellow and the red varieties.

2. Yellow phosphorous is a colorless, transparent to translucent, wax-like solid. At ordinary temperatures it is sufficiently soft to be cut with a knife, but at lower temperatures it becomes more brittle.

3. It burns the flesh when handled out of water, and these burns are slow to heal, on account of the poison absorbed. For this reason this element should always be manipulated with a pair of forceps.

4. It is insoluble in water. It is soluble in 350 parts of absolute alcohol at 15° C, and in 240 parts of boiling absolute alcohol. It is soluble in 85 parts of absolute ether, in 25 parts chloroform, and in about 50 parts of any fatty oil. Carbon-disulfid is probably its best solvent, dissolving from 18 to 20 times its weight without losing its fluidity. All solutions of phosphorous in carbon disulfid should be preserved with the greatest care. When spilled or otherwise exposed, the solvent rapidly evaporates, leaving the phosphorous in such a finely divided condition that it inflames spontaneously.

5. It possesses a garlic odor, and is very poisonous. This odor somewhat resembles Ozone.

6. The phosphorescence, visible in the dark, when exposed to the air appears to be due to the slow formation and spontaneous combustion of phosphin.

7. Phosphor is a very inflammable element, igniting spontaneously in air at 50° C. For this reason it is kept and cut under water. Phosphor, when kept under water and exposed to the light, undergoes slow oxidation, becoming covered first with a white, opaque film, which slowly turns red.

FIRST PRIZE, $3.00

SIMPLE ELECTRICAL ALARM CLOCK.

Herewith are submitted the details for an electrical alarm clock which I believe is the simplest one I have seen published in your valuable magazine. A brass spring (a) is supported on an insulating block (C). A piece of blotting paper is glued on to the end of the strip to insulate it from the alarm-winder. The operation of the alarm can be easily understood. When the clock alarm rings, winder key revolves which releases the spring. When the spring is released it strikes against the side of the clock, thus closing the circuit.

UNIQUE "HOOK-UP" FOR TELEGRAPH SETS.

Herewith is a hook-up used by myself and friend on our telegraph sets, the main object being to eliminate closed circuit cells and to use dry cells. When one fellow wishes to call the other he opens his key and throws his switch over to "receive" and closes his key. The apparatus used comprises two sets, i.e., sounders and keys; two D. F. D. T. switches, 2 sets dry cells (3 each). Our system works fine and the extra-switch throwing is worth the battery saving.

Contributed by G. E. MEARS.

SECOND PRIZE, $2.00

A "COLLAR BUTTON" COMPASS.

This compass is very easy to construct, and can be made with a needle, collar button, snap fastener, and a piece of thin steel, cut in the shape of a compass needle. After having cut the needle to the desired shape and size, punch a hole in the center. Over this solder the bottom part of a snap fastener. This completes the needle. Next, force a steel needle up through the collar button so that it protrudes out of the top about one-sixteenth of an inch. Solder it firmly from the under side. The needle is magnetized by rubbing it over a magnet. When it is thoroughly magnetized, place it on the needle point and adjust it so that it will balance and revolve freely. It can be mounted either in or out of a case as desired. I find that an old dollar watch back makes a good base as it does not affect the needle. This compass is very handy for performing experiments.

Contributed by J. H. ENGLAND.

KNOWS FOR ROTARY SWITCHES.

Knobs for rotary switches may be easily made from the stoppers on old storage batteries. This is done by cutting the part off which has threads on it and drilling a hole large enough to put a brass bolt thru, as shown in sketch. (Vent stoppers may be purchased from garages.) See cut below. Contributed by MARION HENSEL.

THIRD PRIZE, $1.00

FIXT CONDENSER IN A SHAVING STICK TUBE.

An efficient and neat fixt condenser can be made from a nickel-plated shaving stick can as a container. First cut some tinfoil to about 2 foot lengths and 1-3/4 inches wide, separated by 2-1/4 inch width paraffined paper. This can be made as large as desired, and by heavy pressure a large condenser can be placed in the tube. Solder all lugs and make connections with flexible conductor to binding posts. Bore holes in the cover and make washers as in (B). Fill the case with molten paraffin wax. Contributed by E. S. HAGEMANN.

A SERIES BUZZER TELEGRAPH SET.

Here is an efficient series buzzer telegraph system. When the set is not in use put switches on No. 2, then when you wish to call up your friend put your switch on No. 1, disconnect the key switch and start sending. As soon as your friend hears your signal, he puts his switch on No. 1, thus increasing the battery strength. Remember to reverse the batteries if it is positive at your switch on one end, make it negative at the other station.

Contributed by PRESCOTT OVERTON.
AN ELECTRIC FIRE DETECTOR.

Herewith is a plan of a fire detector which I made myself. It consists of two batteries, a cigar box, an electric bell, a scheme, and a rock crystal. A small reed relay is fastened to the lower contact block, thus ringing the bell.

In Case of Fire the Heat Expands the Copper Wire Spiral, Causing It to Touch the Lower Contact Block, Thus Ringing the Bell.

A piece of bare copper wire made into a spiral spring, two blocks of wood, four screws, and two binding posts. Normally the wire made into a spring does not touch the lower contact block, but when fire breaks out it expands the wire spiral and completes the contact, causing the bell to ring.

Contributed by JOSEPH WOHLPART.

SPARK PLUG TESTER MADE FROM SPARE PLUG.

Most autoists carry a spare spark plug in their tool chest which can be made to serve as a spark plug tester without destroying its usefulness.

The only thing necessary is to cut a piece of fiber or heavy cardboard to the shape shown in the illustration. The hole in the end is made large enough to pass the threaded end of the plug and serve as a holder.

To test the plug in the engine, hold the spare plug, sparking points up, by means of the fiber strip. Touch the post on the plug to the engine cylinder and bring the thread end of the plug in the plug against the binding posts of the plug in the engine.

A small spark or none at all will indicate a broken porcelain or carboned and short circuited plug. A heavy spark will show that the points of the plug in the engine are too far apart. In cases of emergency any means may be employed that will hold the test plug without giving the driver a shock.

Contributed by THOS. W. BENSON.

TWISTING CABLES IN THE SHOP.

In looking over your October, 1916, issue under the head of "How-to-make-it," I noticed a scheme for twisting telephone wires, contributed by Mr. Leach. While this is a good method, I would like to suggest one that will not ruffle or twist the insulation of the individual wires as other methods do.

Porcelain knobs may be used as swivels. Attach two knobs to shop wall, do not tighten up screws, knobs should turn freely. Attach No. 14 wire loops to receive ends of insulated wires. Have wires same length; turn brace five or six times, pulling on it to take up slack and keep knobs from turning. Now slack off slightly on brace and knobs will spin, thus relieving the twist in each individual wire. Almost any length of wire can be handled in this manner, equaling the factory product.

Contributed by J. ESHLIMAN.

A REVERSING SWITCH FOR SMALL MOTORS AND TOYS.

A small but thoroughly effective reversing switch for small battery motors and other apparatus can be made from scraps found about most any workshop.

First procure a base about 1/2" square and 1/4" thick. Next cut four strips, each 3/4" long and 1/4" wide out of a piece of brass about 1/16" thick. Then bore a hole in one end of each strip and fasten it to the base by means of small wood-screws as shown in Fig. 1.

Contributed by HENRY RHEIMS.

DRAFTING HINTS.

Tracings may be very readily cleaned and pencil marks removed by the use of benzine, applied with a cotton swab. It may be rubbed freely over the surface without fear of injury to the lines drawn in ink, or even water colors, but pencil marks and dirt will quickly disappear. The benzine evaporates almost immediately, leaving the tracing unharmed. The surface, however, will be somewhat softened, and should be rubbed down with a little powdered talc or chalk before drawing more ink lines. Always sprinkle chalk or talc on surface (dull side) of cloth, rub in with fingers, and wipe off before starting to draw ink lines.

SIMPLE HOME-MADE SNAP SWITCH.

This is a very durable but simply constructed snap switch. (A) is the screw from an old dry cell carbon, the head (E) being filed flat and inserted in a small block of wood (I) drilled as shown. The block (I) is fastened to wood base (G) with screw (B). A strip of spring bronze (D) inserted thru the slot in spindle (F) assures an excellent contact. (C) is a pin for handle and (H) the supporting screw holes. The spindle is held in the base by a small rivet at the bottom. This can be used either as a single or double-pole switch.

Contributed by WALTER SELLENEIT.

HOW TO MAKE A S.T.D.P. SWITCH OUT OF TWO S.P. KNIFE SWITCHES.

Nail a block of wood on to a base of proper size. Next procure two S. P. battery knife switches. It must be made certain that one opens to the right and the other to the left. The reason for this can be seen when they are mounted. If they are the same, just take off the knife and terminals and remount them in reverse or...
SPIRIT LAMP FROM FAN GREASE-CUP.
A novel but efficient spirit lamp can be made from a fan grease-cup when cleaned and filled with alcohol and a wick inserted.

Simply Fill a Fan Grease Cup with Wood Alcohol, Insert a Wick in the Hole, and You Have a Serviceable Little Spirit Lamp for Light Soldering.

It will burn for one hour. This lamp can be used for numerous purposes, such as removing enamel from enameled wires, et cetera. A small brass tube can be easily soldered to the cup for the purpose of providing a blast of air and a side-wise concentrated flame tip, by blowing thru the tube. The upper end of the tube must be closed, and a tiny hole drilled in it—about No. 64 drill.

Contributed by EDWIN WOLBER.

SOME INTERESTING CHEMICAL EXPERIMENTS.
When a very little dry powdered potassium permanganate is moistened with sulfuric acid, brownish-green oily drops of permanganic anhydride (MnO₂) are formed. This compound is volatile, giving a violet vapor and is apt to decompose explosively into oxygen and manganese dioxide. Its oxidizing power is such that combustibles like paper, ether and illuminating gases are set on fire by contact with it.

White phosphorous, when heated with sulfur unites with explosive violence. By using red phosphorous the action can be controlled. The product is phosphorous sulfid and the kind depends upon the proportions used.

If a small piece of sodium is placed on a piece of filter paper and placed on water, the water is decomposed and the heat liberated is sufficient to set fire to the sodium, which burns with a characteristic yellow flame.

Powdered magnesium and potassium chlorate in the proportions of 10:17 is used in making flashlights for use in photography. Cordite, a variety of smokeless powder, is made by dissolving guncotton (65 parts) nitro-glycerin (30 parts) and vaseline (5 parts) in acetone. The resulting paste is rolled out and cut into small pieces. When the acetone evaporates the horny cordite remains.

Javelle water (solution of sodium hypochlorite) is an ingredient of ink eradicators. The solution is first applied to the ink and a dilute solution of hydrochloric acid is rubbed over it. The chlorine which is liberated is responsible for the bleaching effect.

Contributed by ALBERT TOTHL.

TEST CLIP MADE FROM BINDING POST.
For making contact with insulated wires take an old binding post and file the thumb screw to a point. Also cut a portion of one side out with a hack-saw as shown in the drawing. To make contact with an insulated wire, simply slip the wire in the slit in the side and force the thumb screw point through it. This will save the time and bother of skinning the wire. It also may be used as a helix clip.

Contributed by MERLE E. NANTZ.

FITTING A MINIATURE BULB TO STANDARD SOCKET.
First we need a broken Edison bulb, a miniature lamp and some sealing wax or paraffin. Then break all the glass from the bulb, making it to the bottom of the large lamp base. Now solder the two wires from the Edison shell to the rim and center of the miniature bulb. Heat some sealing wax in the bottom of the shell and let it cool. This attachment will be useful to anyone who has a socket with a snap on the side or a pull-chain socket.

Contributed by STAN. DIRVIN.

At Left: Standard Lamp Base Fitted to Miniature Lamp. At Right: Handy Test Clip Made from Binding Post.

CHEMICAL EXPERIMENTS.

No. 1: Put on a clean white plate or saucer, a mixture of pulverized sugar and potassium chlorate. Upon adding a few drops of sulfuric acid a vivid combustion will ensue. By adding with the sugar a few iron and steel filings, and performing the experiment in a dark room, or out of doors at night, bright rosettes will flash thru a rose colored flame, and produce a fine effect.

No. 2: Mix a teaspoonful of nitric acid with a teaspoonful of sulfuric acid; place a little turpentine in a teacup out of doors, and pour the mixture upon it at arm’s length. The turpentine will burn with almost explosive violence.

No. 3: Make a saturated solution of sodium sulfate (Glauber Salt), in warm water; pour the mixture in a bottle, and let it stand. The salt will remain for months without crystallizing; but if taken up, and shaken a few times, the whole mass will instantly form into crystals, so filling the bottle that not a drop of water will escape. Should there be any hesitation at the moment of shaking, drop a small crystal of the salt into the bottle, and the effect will be instantly seen, by the depositing of new crystals in every direction.

No. 4: Heat a piece of tin until the coating begins to melt; then cool quickly in water and clean in aqua regia. The surface will be found covered with beautiful crystals of the metal.

No. 5: Pour dilute nitric acid upon bits of tin. Dense red fumes will pass off.

No. 6: Throw crystals of any nitrat on red hot coals; they will deflagrate with dense red smoke.

Contributed by GLENN HELWAGEN.

PERCENTAGE SOLUTIONS.
The difficulty about percentage solutions, says Studio Light, will disappear if the worker will always bear in mind that one ounce of water weighs 437½ grains, which is, of course, equivalent in weight to one ounce avoidius. It follows that if one-tenth that number of grains—i.e., 43.75 grains—are put into a graduated glass and water added to make up one fluid ounce, the result will be a 10% solution.

In the following table the figures are worked out for solutions of various strengths. If the number of grains indicated in the table are taken and sufficient water added to make up one fluid ounce, it will be found that the solution has the required strength.

No. a 1% solution take 4.37 grains
  5% "  21.82 "
 10% "  43.75 "
 20% "  87.50 "
 30% " 131.25 "
 40% "  175.00 "
 50% "  218.75 "

HOW TO FILE SOFT METALS.
The teeth of a file are soon filled when the file is used on lead, tin, soft solder or brass. It cannot be cleaned like the wood rasp by dipping it into hot water, but if the file and the work are kept wet with water, there will be no trouble as the already wet particles of lead, soft solder, etc., do not readily adhere to the file.

HANDY COMPUTER FOR MECHANICS.
Here’s the latest vest-pocket computer for electrical and mechanical men. By rotating the cap on end it shows at a glance the size of drill to use for taps for sizes from 1/4 to 2 inches. U. S. S. Pipe 3/4 to 3½ inches. A. L. A. M. to 1 inch. S. A. E. to 1½ inches also 15 small numbered sizes below 1½ inches. It has the advantage over blue-prints and chart that it can be easily carried in the vest-pocket.

A Useful Computer for Machinists and Experimenters. It Shows the Size of Drill for Any Tap Instantly.
Loose Coupler
(No. 1,276,618, issued to Carlyle B. Canyon)
This patent relates to an improvement in tuning transformers and particularly to a switching arrangement by which unused portions of the inductance or winding are completely cut off from the circuit, thereby eliminating undesired effects on the wave length. The arrangement shown provides for a plurality of separate coils in close inductive relation. The terminals are connected with solid and spring contacts, adapted to be separated by a revolving insulating disk in order to cut out certain coils when so desired. In other words, it incorporates a revolvable form of dead-ending switch.

Electrically Heated Radiator
(No. 1,276,637, issued to James J. Rohan)
An electrically heated steam radiator of novel design in which there is provided a radiator of the usual form, together with an electrically heating steam generator, this latter being very rapid and economical in operation, it is claimed. Simple and positive means are provided for automatically controlling the flow of electric current to the heater, and likewise for automatically controlling the flow of water of condensation from the radiator back to the heating device; this automatic control being effected through the medium of the steam pressure developed within the heating device.

Electric Shutter Trip for Cameras
(No. 1,277,592, issued to Gilbert R. Horton and John M. Miller)
By means of this electromagnetic actuating mechanism for camera shutters, photographs may be taken at a considerable distance from the operator, such as where animals are to be photographed. The length of circuit over which this shutter device may be operated is governed only by the strength of the battery used. A push button, which is located at the battery, the current completing a circuit thru the small electromagnet fitted to the shutter trip as shown. When the magnet is actuated the shutter is opened, continued pressure on the push button will hold the shutter open.

Electric Headlight
(No. 1,276,665, issued to Overton Campbell, Wisc.)
An improved electric headlight for automobiles and other machines and providing a special means for shifting the electric light bulb with respect to the reflector, whereby the bulb may be moved transversely toward and from the axis of the reflector. A soft iron or steel collar is secured to the rear end of the lamp base, which serves as an armature in cooperation with an upper and lower control electromagnet. These electromagnets are secured to and supported by an annular ring mounted in the lamp housing back of the reflector. Thus the lamp bulb proper may be thrown up or down, simply by actuating one or the other of the electromagnets, throwing the light beam either far ahead of the machine or else just in front of it on the ground, as may be desired.

Apparatus for Concentrating and Projecting Radiant Energy
(No. 1,278,028, issued to Salvatore Salto)
An apparatus for the concentration of light, heat and electric rays and for the projection of these rays in a certain desired manner. This apparatus for concentrating and directing light rays has for its purpose to illuminate objects by concentrating light rays thereon, by means of reflectors with elliptical curvature. The object to be examined or illuminated may be observed directly by placing it inside the hollow elliptical, or projected on a screen by means of a suitable device such as a microscope or a magnifying glass. Thus extremely high specific luminous or caloric intensities are obtainable by concentrating emanations from several sources of energy and causing them to be projected on a screen. Thus, for example, in the case of a light source, the light, or as a projector for motion picture machines, automobile head lights, etc. The apparatus can also be used for concentrating heat radiations.

A Sound Operated Dog
(No. 1,279,831, issued to Christian C. Grober)
When you clap your hands or whistle to this "pup" he jumps out of his kennel in great delight. All because of a clever arrangement of a simple microphonc and electromagnet which holds the trip retaining the dog within the kennel, until the sound produced by the clap of the hands or whistle strikes the microphone. At this instant the normal constant current thru the retaining electromagnet drops to a comparatively low value, thus releasing the powerful spring which kicks "Fido" out the door.

Primary Battery
(No. 1,276,74, issued to Walter Grothe)
A novel arrangement for supporting the electrode elements within a primary battery. The supporting member for the electrodes consists of a flanged yoke having depending ends, while a suspending bolt passes thru a hole in the yoke and is rivetted therein. A spool of porcelain is arranged to be clamped against the yoke as shown. The shank and heads are preferably of triangular shape. A perforated container closed on all sides excepting the top, is adapted to be clamped between the depending ends of the yoke and the ends of the clip.

Crystal Detector
(No. 1,277,637, issued to Thomas H. Miller)
A crystal detector for radio receivers which is claimed to be exceptionally rugged and reliable in design; also its operation is not likely to be interfered with by mechanical jars or concussions. This adjustable feature enables the contact member to be placed at any point upon the surface of the crystal desired, and the contact point and crystal are both enclosed.

Motor-Driven Revolving Door
(No. 1,276,145, issued to Edward C. Haviland)
Where a revolving door is continuously rotated, electric current is being continuously consumed regardless of the egress or ingress of people thru the door. The object of the present invention is to provide a means whereby a motor for revolving the door is only put in operation when a person is passing thru the door. These switches eliminate electrical circuits to the actuating motor, but only for such time as is necessary for the person to pass in or out of the door.

Radio-Telegraph Transmitter
(No. 1,279,500, issued to Oscar C. Boss)
A system in which the discharge of the oscillating circuit condenser may be readily controlled over a wide tune range. The operation is as follows: The high frequency generator A cannot break down a larger gap than S and the arresters, therefore prevent the discharge of the condenser C across the gap unless they are simultaneously broken down. They...
"Amateur Electrical Laboratory" Contest

THIS MONTH'S $3.00 PRIZE WINNER—ALFRED STACEY

HEREWITH are photographs of my laboratory. On the large table in the center of the room may be seen the radio outfit which was assembled in its original place to take this photograph. When set up it was used with an aerial one hundred and fifty feet high, one hundred feet long, with four stranded wires placed three feet apart. The transmitting set consists of a 15 K. W. transformer, condenser, rotary gap, oscillation transformer, aerial inductance, aerial condensers, and hot-wire meter, keys, etc., also a Polsen arc and transmitter for radiotelephony. For receiving, I have receiving transformers, variable condensers, flat condensers, audion, loading coils, Ferron, Galena, and Silicon detectors, two pairs of 'phones, etc. On the experimental table to the left of the radio table may be seen Tesla, audion, step-up and step-down transformers, meters, batteries of different types, motors, generators, telegraph and telephone instruments, condensers, measuring instruments and other electrical apparatus. To the right of this apparatus may be seen the two switch-boards containing circuit breakers, switches, and rheostats for controlling various instruments. To the right of the switch-board may be seen the work-bench for building and repairing instruments. To the right of work-bench, chemicals, elements, retorts, graduates, flasks, hydrometers, thermometers, ad infinitum. To the right of this bench will be seen another bench used for the manufacture of chemicals such as bromin, chlorin, etc. Next may be seen the stock-room and dark-room used for photo developing and printing. I have a book-shelf containing over one hundred and fifty chemicals and electrical books. This laboratory is the result of ten years' hard work assisted by the famous "Electrical Experimenter" and "Modern Electrics."—ALFRED STACEY, Hamilton, Ontario, Canada.

HONORABLE MENTION (1 Year's Subscription to the "ELECTRICAL EXPERIMENTER") GERALD DITTMAN

I PRESENT herewith photograph of myself and two of my laboratories. I am eighteen years old and have had my laboratory for about a year. I have a great number of chemicals which I use for testing foods and for mixing up different solutions to see what effect they have on electricity. I have made an arc light which furnishes all my illumination. I use an ammeter to show how much current I am drawing and in that way save fuses, because when the pointer approaches ten amperes, I know a fuse will blow and I can shut it off in time. I also have a number of motors, a transformer, spark coils, condensers, Leyden jars and other instruments which I use for various experimental purposes.—GERALD DITTMAN, Chicago, Ill.
Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! We PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner: WEEWEEEPICORGAN. Take one gross pigs fresh and lusty, assort according to musical scale, put each in soundproof chamber, attach tails to electromagnetic claws operated by keyboard. Pigs run on endless belts furnishing power for organ. Depressing keys on keyboard pinches pigs' tails. Pig sings weee—weeee—wee, as long as key is pressed. Don't use old sows. They sow discord. French airs go well on this organ due to the oui, oui! Inventor: Paul Gaugewere, Bethlehem, Pa.
The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one question may be written on each sheet; no penciled matter considered.
3. Drawings, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail free of charge.
4. If a quick answer is desired by mail, a nominal fee of 105 cents is made for each question. If the questions entail considerable research work or intricate calculations a special rate will be charged. Correspondents will be informed as to the fee before such questions are answered.

FIRING TWO FLASH-LIGHT POWDER PANS SIMULTANEOUSLY.

(970) Fred Wheeler, Galt, Ont., Can., wants to know:
Q. 1. How to fire two or more flash-light pans simultaneously.
A. 1. For firing flash-light powder at two places simultaneously, we refer you to arrangement as per diagram. Use a spark coil and battery as indicated in diagram. Wire the two or more flash pans in series. Keep the spark gap in each pan small—1/16" gap is sufficient.

HOW TO TELL DYNAMO POLARITY.

(971) Paul Miles, Chicago, Ill., inquires:
Q. 1. How can the positive terminal of a small D. C. dynamo be determined?
A. 1. Off-hand we cannot tell you which is the positive brush. However, we advise you to make the following test: In a 50% solution of salt water put two wires connected to the dynamo, and note from which wire the most bubbles come off. This is the negative wire.

A 4-volt dynamo will give about 3 amperes. However, much depends upon the condition of the brushes (contact, pressure, etc.), and the condition of the batteries. We would advise you to refer to "Lessons in Practical Electricity and Magnetism," by Swope, which can be purchased thru our Book Department for $2.25, postpaid.

SPEED CONTROL OF A.C. MOTORS.

(972) Hugh McPherson, Borden, Sask., Can., asks:
Q. 1. How can I control the speed of a 30 H.P. A.C. 3-phase motor?
A. 1. The speed of the 30 H.P. A.C. 3-phase motor can be regulated in several ways, some of the best of which are as follows:

The voltage applied to the motor is varied by a transformer from which several taps are brought out to a controller, thereby varying the speed. Again, by means of an induction regulator which consists of a primary and secondary winding, having an iron core with one of the windings so arranged as to allow of being varied thru 180 magnetic degrees. The above methods are really best for single-phase service, while the following method is very good for the three-phase service: In this method the speed can be varied by changing the number of poles of the motor connected in the circuit by means of suitable switches or by varying the current by a suitable rheostat connected in the respective legs of the wound rotor circuits. This last method also applies to the single-phase system, wherein the current is varied by means of a rheostat.

LOOSE COUPLER AND DISTRIBUTED CAPACITY.

(973) C. W. Opert, Freeport, Ill., wishes to know:
Q. 1. Several points about making a loose coupler transformer for radio receiving circuits.
A. 1. In constructing a loose coupler, the best way to take the taps off is as follows: At the required part of the coil put a hole in the cardboard tube and soak about 18 inches of wire thru this hole by looping the wire, and then pushing it thru. All that remains to be done now is to continue winding the coil until all the taps have been made.
We provide coils with dead-end switches in order to get rid of the distributed capacity. Distributed capacity is the capacity which exists between the turns of a helical coil, and for your benefit we refer you to an extensive article on this subject which was printed in the May, 1917, issue of this journal.

TESLA COIL FOR 2-INCH SPARK COIL.

(974) R. Conover, New York, N. Y., inquires of "The Oracle":
Q. 1. For data on a Tesla coil suitable for use on a 2-inch spark coil as an exciter.
A. 1. The ordinary Tesla coil, especially designed to work with a spark up to 2 inches on the primary side will do, and is briefly described as follows. The primary should consist of 14 turns No. 10 solid, rubber-covered copper wire in one layer on a spool 4½ inches in diameter, while the secondary consists of a coil 2½ inches in diameter and 12 inches long, wound its full length with a layer No. 28 enamel wire.

This size of Tesla coil can be furnished by the leading companies who advertise in our magazine. It is best to use two one-pint Leyden jars connected in parallel or a one-quart Leyden jar.

The construction for a glass plate condenser for the above Tesla coil is as follows: Procure five glass plates 6x7x1/16" and four pieces of tin-foil 5x6 inches. The tin-foil should be placed between the five plates so that two ends of the tin-foil protrude from the sides of the glass. The size of the space remaining from the above Tesla coil will be about ¾ to 1 inch and can be taken thru the body without any harm.

Free Test Lesson in Draftsmanship

Send for this free lesson which explains the Chicago "Tech" method of teaching Draftsmanship by mail. Positions at big salaries are now waiting for competent men. The call of men to the war has left vacancies everywhere. Even draftsmen of limited training and experience are snapped up and paid good salaries. If you are dissatisfied with your opportunities, learn Draftsmanship. Chicago "Tech" will train you in the most practical way in the shortest time. Mail the coupon today and let us tell you about the Chicago "Tech" method. This free lesson will show you how well equipped you are to follow Draftsmanship. Enroll in the course only if you decide that you can take it up to advantage. No cost, no obligation on you to make this investigation.

Come to the College or Learn At Home

Hold your present position while training. Our experts will instruct you by mail. Only your spare time is required. You are directly under practical draftsmen and engineers. You are taught exactly the work required in the drafting rooms of big concerns. No time to put in on unnecessary studies. This means thorough instruction and early graduation.

$25.00 to $100.00 a Week

Draftsmen earn good salaries in normal times. They command extra high salaries now—and the tremendous work to be done after the war will bring a permanent and intensive demand for good men. Make your spare time count now for a higher salary and a better position.

Easy Payments

The fees for Chicago "Tech" Courses are very moderate—and you can pay on easy terms. And also—you obtain in a few months what it would take several years to acquire by ordinary methods. You can get an early start. You are soon ready to take a paying position and to quickly get back the cost of your course.

Send the Coupon

The sooner you are prepared the sooner you will be holding a job that pays a large salary and opens the way to advancement. Many executives, general managers and superintendents began as draftsmen.

Other institutions ask you to pay first—and then to find out later how well qualified you are for this profession. We send the free lesson first and place you under no obligation at all. Discover your qualifications before you pay anything.

The coupon will bring the Test Lesson, free. Also information about the profession of Draftsmanship and detailed facts about Chicago "Tech" methods, the fees, terms, etc. Mark X the branch you are interested in—or if in doubt about which course to take, write a letter stating facts about yourself and asking our advice which will be freely given. Mail either the coupon or the letter today.

Auto and Gas Engine Course

All about automotive mechanism—construction, operation and repair. You train directly under the Chicago automotive experts.无以名之 opportunities open now.

Learn All This In Spare Time

Principles of the Automobile.
Every part made clear about the basic principles of automobile-performance and repair. Gasoline Engines. All about the different types... Complete course in gas engine construction, operation and repair.

Power Plants and Transmission. Application of power, by 4-6-8 cylinder engines, types of transmission. Gears, chain, etc., used in transmission. Principles and practice of different systems. All methods of... Gasoline and air mixtures. Reguration, etc., etc.

Lubrication and Cooling. All about oil and how to use them. Splash and circulating systems. Operation in different cars at different times.

Lectures on electricity. Electrical principles explained. Instruction diagrams. Wires and connections, etc., etc.

Lectures and Lightning Systems. Electrical and magnetic spark. Mechanical, air, scintilator, etc. Safety rules given in detail with diagrams and full explanations. Changing voltage and generator adjustments, etc., etc.

Know How to Fix Troubles

Most expensive work in auto repair work. Equips you for high pay or in start in business. Big demand for trained repair men.

WRITE

Send the coupon and get catalog and all information now.

FREE Instruments

Every student of the Chicago "Tech" Course in Draftsmanship receives this set of instruments, or a cash credit in case he already has a set. These instruments are of the same make and sizes as used by high salaried experts in drafting rooms of factories, shops, railroads, etc. You use them while learning—then take them right into your practical work.

Chicago Technical College,
145 Chicago "Tech" Building, Chicago

Without obligation to me, please send me your FREE Test Lesson and other interesting literature covering the school indicated below. Mark X opposite work in which you are especially interested.

ELECTRICAL EXPERIMENTER

THE ORACLE.

(Continued from page 646)

RECORDING SPEECH ON A MOVING IRON WIRE.

(975) Miss Clara B. Griffin, Carthage, III., writes this Department:

Q. 1 Can an instrument known as the Telegraphophone record speech?

A. 1. Relative to your inquiry regarding the Telegraphophone, an instrument invented by Valdemar Poulsen of Denmark, we are pleased to state the following:

This instrument will record speech on a thin steel wire by recording the fluctuations of the magnetic lines of force set up by a set of magnet coils. A full description of this machine was given by Samuel Cohen in the June, 1915, issue of this Journal; an article describing iron wire type of Telegraphophone designed as a dictating machine for business offices.

CHARGING LEYDEN JARS.

(976) Mr. B. Brewer, Dedham, Mass., asks:

Q. 1. Different ways to charge Leyden jars.

A. 1. We are giving a sketch herewith to show how to charge the ordinary Leyden jar by means of a static machine.

The best way is to hold the jar in the hand and let sparks from one of the balls of the static machine jump over to the central ball of the Leyden jar. At first the sparks will jump fast, then as the jar becomes charged, they will grow smaller and smaller, finally being too small to discharge. The ordinary machine, as shown in Fig. 2.

The important part to remember is that not every glass can be used for Leyden jars. Here is where many an experimenter is disappointed. Only potash glass can be charged — all the other varieties, such as flint and lead glass, “leak” — it being impossible to sustain a charge for even one second if such glass is used in the Leyden jar. If no potash glass is procurable, an ordinary glass jar can be coated on both sides with tinfoil. The jar can be charged by means of the ordinary machine, as shown in Fig. 2.

Various Ways in Which to Charge Leyden Jar Condensers from Static Machines and Induction Coils.

In order to get the charge, it is necessary to hold the discharger as shown, and a continuous discharge will flow across the two knobs. The quality of the spark is the same whether charged by a static machine or Leyden jars, except that in the case of a static machine the spark will sometimes leap several inches, while the jar charged with a spark coil will only leap an eighth or one-quarter of an inch, and in extreme cases one-half inch.

DOES A PERSON WEIGH MORE AFTER EATING?

(977) Querist, New York City, inquires:

Q. 1. Does a person weigh more after drinking say, 25 glasses of beer, or eating 10 lbs. of beefsteak (as often happens at beefsteak eating contests), or will their weight remain the same? "A. says they will weigh the same; "B. says their weight will increase in exact accordance with the amount of food or drink taken into the stomach.

A. 1. This is an interesting question and one that has been asked hundreds, even thousands, of times. The Editor of this column collects the usual answer by the man in the street to the effect that he will weigh exactly the same. He will, eventually, but—well, listen to the learned

MECHANICALLY RIGHT—A REAL LATHE

A Regular Lathe, not a toy

Swing 4 inches. 15 inches between centers. 18 inches total length. Net weight: 200 lbs. Spindle weight 110 lbs. with tool post. Cuts very hard. Workmanship is first class throughout. Lathe comes speed with metal cutting chuck. Lathe can be fitted with 3 inch face plates and 3 dial head for special equipment. Order one today. Price $25. 50 cash with order.

SYNTHIA MFG. CO., DEPT. C, TOLEDO, OHIO

Feldman’s “Geyser” Electric Water Heater

Instantaneous Hot Water

FELDMAN MFG. CO.

1500 Times Bldg.

New York City

Thousands of skilled Electricians are needed. The demand is becoming more urgent every day. The Government is employing every one they can get which is causing a great scarcity throughout the country and big salaries are being paid everywhere. Right now is your big opportunity. Make up your mind now to prepare for one of these big jobs and then get here as quick as you can for your training.

Earn $100.00 To $300.00 A Month

In the Electrical business. Come here where you will be trained in these great $100,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

The War is Over—Yes!

but the men “over there” will not be back for months—perhaps years, for their work “over there” isn’t over. And so you, and thousands more must fill up the gap now that the absence of these brave workers has made in the ranks of skilled labor. Trained Electricians are needed more, perhaps, than any other class of men. The sudden ending of the war has caused the big industries to start work sooner than any of us expected and in consequence the Manufacturers are Calling for Trained Men, and we are training men as fast as we can to meet these urgent calls. You are needed, Young Man, now! Don’t wait. Don’t put it off. Get in touch with us Today. Get ready to join the great “Peace Army” here at home. Your country calls. Again we say, prepare to serve your country! We’ll make a trained electrician of you in three months! Let’s go!

LEARN DRAFTING

Skilled Draftsmen are always in demand. Our courses are thorough—short—practical, preparing a man fully to hold a position of responsibility. We have more positions than we can fill. We also have thorough practical courses in Plumbing and Heating, Motion Picture Operating and Bricklaying.

EARN YOUR WAY

Many students earn their living expenses by doing a little work in their spare time. Our employment dept. fills these positions without charge.

THE ORACLE.  
(Continued from page 648)

pores of the skin, also from the lungs, this slight difference would occur immediately. But in two or three hours, due to the foregoing causes, also digestion, the weight will gradually decrease to normal.

Dr. William Benham Snow, of New York, one of the leading American electro-therapists and medical men, states: "The increase of weight in the human being after eating, say, one pound of meat varies greatly. In some instances there is no increase at all; while in others there is a slight (but never the full weight) increase, all depending upon an individual's respiratory and digestive organs. In the case of water, the full weight of the water is added to the person's weight, but within a very short time the weight will rapidly decrease to normal. It has been a widespread and popular idea that if a person were to lie on his back and hold his breath he could be lifted with two fingers. This has been done by hypnotism, but not otherwise.

ELECTROLYTIC RECTIFIER.  
Q. I. I have made a small Electrolytic Rectifier for charging storage batteries. This rectifier was built from instructions in the Scientific American Supplement No. 1544. According to the instructions, the liquid consists of one pound of crystallized sodium orthosilicate (per jar).

I am having trouble getting this chemical. Some drug houses I have been to do not seem to know what it is at all. Could you advise me where I can get it? Or what other chemicals I could use instead?

A. 1. Relative to your electrolytic rectifier, would advise that the majority of these rectifiers, even the larger sizes, are operated with a solution composed of sodium bicarbonate (baking soda) dissolved in water until the solution is saturated, i.e., until the water will not absorb any more of the bicarbonate. Another very good solution is composed of water in which there is mixed ammonium phosphate. A saturated solution of this is also electrolytic.

The matter of the solution used is not a very important one, it being more important that a good, pure grade of aluminum is employed. Water and air have been used in electrolytic rectifiers in emergency for that matter, and also wherever a solution seems to have a high a resistance or where a sufficient current is not obtained, a few drops of sulfuric acid may be added to the water to make it more conductive. If you have further trouble in getting the rectifier to operate, it is well to note that the aluminum plates have to be formed" and this has sometimes to be accomplished by running the rectifier for five or ten minutes or so connected to a lamp bank so that this or similar resistance in the line can put a fairly strong current thru the rectifier, and cause the necessary oxid to form on the aluminum electrodes.

2 K.W. "PIPE THAWING" TRANSFORMER.  
(1979) Mr. Wm. E. Newton, Ontario, Canada, writes the "Oracle" Dept.:

Q. I. I would like to make a transformer for Ordinary water pipes and want a secondary current of 150 amperes at 10 or 12 volts, as I would only need to thaw about 10 or 12 feet at a time. The primary winding will be operated by 110 volts, 5 cycle alternating current. I have plenty of soft pipe iron at hand from which I could make the core, which, I suppose, would be of the closed core type. Please give dimensions of core, size, number of turns, and weight of wire required for primary. What kind, size, number of turns of wire required for secondary core, etc. A. 1. We give below data for constructing the transformer in question:

Primary: 2 loops of No. 9 B. & S. gage D. C. copper magnet wire wound in layers on one of the long legs of the core. This will require about 2 pounds of wire.

Secondary: The secondary coil to deliver 150 Amp. and 13.3 volts at full load may comprise 31 turns of No. 0 B. & S. gage D. C. copper magnet wire, or if this is not convenient, owing to its large size, you may wind on simultaneously two No. 3 B. & S. gage D. C. conductors side by side, or four No. 6 B. & S. gage D. C. conductors. The terminals of the separate wires, if a multiple winding is used, are joined together so as to connect all the wires on parallel.

The efficiency of this size of transformer is about 95 per cent with respect to the watts input at the primary and the watts output at the secondary.

Knowing the size of the core you can readily compute the weight of wire for the windings by consulting any wire table. The circular mils area of the No. 9 B. & S. gage wire is 13,594 c.m., while the circular mils area of the No. 0 L. & S. gage conductor is 105,592 c.m.

A NEW TOGGLE SWITCH.  

The toggle surface switch illustrated differs from the ordinary snap switch in that manipulation is by the throw of a lever or toggle, instead of by the turning of a key or button. Throwing the lever up makes the circuit; throwing it down breaks the circuit. The movement is positive—the make-and-break quick and snappy. The toggle switch has been used in Europe for a number of years, but was slow to find favor in America. 

The advantages of the toggle movement in a surface switch are stated as three-fold—first, it permits making the switch more attractive and stronger than the ordinary switch; second, manipulation is much more convenient by means of a toggle, and third, the switch is self-indicating, the position of the lever showing at a glance whether the current is "on" or "off" without any marker or dial. It combines in unusual degree the best mechanical advantages of the features which make an appearance which makes quick appeal to those seeking the dignity of simplicity and richness.
RADIO-TELEPHONE GUIDED U. S. FLYERS MANY MILES AWAY.

(Continued from page 629)

require amplifying more than from ten to fifteen times.

Fig. 3 shows a new form of oxid filament tubular audion as supplied on U. S. Army and Navy sets. This bulb is provided with a special base, making it very convenient for attachment or replacement, and tests made with this bulb show the life to be about five thousand hours.

Fig. 4 shows an improved form of audion control panel. A number of new radio-engineering features are incorporated in this apparatus, including deeply grooved, insulating terminal blocks which carry the binding posts. Integrating condenser switches are employed for regulating the capacity of the bridge and stopping condensers. The ammeter at the right of the panel indicates the filament current at all times. A special form of graphite potentialmeter is mounted just below the filament ammeter to regulate the wing current.

Fig. 5 shows a large capacity oscillation bulb and control instruments mounted on a self-supporting panel for radio-telegraphic transmission. The bulb is mounted between upper and lower rings of heavy, rubber-covered wire. The loading coil switch for varying the antenna wave length is mounted in the upper left hand corner of the panel. Terminals for the Morse telegraph key are fitted at the bottom of the panel. A radiation hot-wire ammeter is seen at the left of the switchboard, while a three-pole switch controlling the filament and wing current appears at the right. The necessary condensers and auxiliary apparatus are compactly mounted on the back of the panel.

A $\frac{1}{2}$ K. W. oscillation is good for 150 miles radiophone transmission over water, or 250 miles radio-telegraph signaling over water. A 1 K. W. outfit has a range of 200 miles radiophone or 300 miles radio-telegraph over water. A 2 K. W. will talk 300 miles or telegraph 400 miles over water. These ranges can be greatly increased by the use of two to six stage audio amplifiers. The six stage audio amplifier has an amplifying factor of one million times.

Fig. 3. New Form of Oxid Filament Audion as Supplied on U. S. Army and Navy Radio Sets.
ELECTRICAL EXPERIMENTER

SALT FROM THE SEA BY ELECTRICITY.

A company is about to start the exploitation on a large scale of a method for extracting salt from sea water. The undertaking is being backed up by a number of men of exceptional standing. The process is due to Professor Helledan Hansen, and the venture is backed by $5,000,000. It will in all probability be found expedient to erect several works along the coast of Norway as way more electric energy becomes available.

The comparatively large capital is principally necessary on account of the large plant needed, preparing solutions, etc., absorbing the bulk of the power; the production of the salt itself only requires a small amount of energy and is consequently cheap. As to the location of the new factories, no definite decision has been arrived at, but Stavanger has been mentioned as a likely place for the first factory, and the Giamfjord for the second.

A MELODIOUS PHONOGRAPH REPRODUCER.

By Frank C. Perkins.

The accompanying illustrations show the details of construction of a new phonographic reproducer, developed at Milwaukee, Wis., which is said "Humanizes a Talking Machine." This machine is so arranged that the phonographic reproducer plays perfectly all disc record selections, even the subtle tones of the instrumental accompaniments and prevents clash and approaches the living voice, whether of soprano, contralto, tenor, baritone or bass, quite as natural as life. Even the resonator of the violin and the tone of the flute are marvelously perfect.

It is held that band records are reproduced with all the tone values of instruments, every overtone and undertone brought out harmoniously, without nerve-wracking tire, while orchestral combinations are greatly improved. The recordings of the great symphonies are revivified with all the original sublimity; intensified in just the right volume for home enjoyment. The violins, cellos, cellos, clarinet, bassoon, saxophones, flutes, piccolos, horns, the "brasses" including the great tuba, the "percussion" containing drums, cymbals, bells, special effects as the imitation of birds, church choirs, are all as real as the record is made.

Any talking machine can be equiped with this reproducer in a moment, without tools. Either steel or fiber needles will work perfectly with the reproducer, whose weight is less than four ounces, so that records wear indefinitely if care is used.

BOOK REVIEW

The student of electricity and magnetism will find many new, interesting, and valuable experiments described in this work. The author is well known for his scientific circles and of high standing. Furthermore, as it seems to the present reviewer, this presentation is of more than ordinary interest, as involving experiments in the laboratories and spark shadows are given with some new theories as to their meaning; causes of local magnetic storms; the effect of "wind" on magnetism; and something on the relation of sounds. These effects are indeed wonderful, and so new as to demand the attention of every earnest electrical student. Professor Nipher has performed some very interesting experiments in the laboratory and also in the field along these lines, and if you wish to read something refreshingly new in the realm of experimental electricity, you should by all means study this excellent and clearly written explanation of these little known scientific phenomena.

One of the well-known Horstmann and Tousley practical handbooks for electrical engineers giving the theory and practice of this branch of electrical engineering so that the nonspecialist can learn the exact meaning of the various terms used. The work starts with the generation of alternating currents and discusses induction, power, capacity and resistance and their effect on the voltage and current in alternating current; we find an interesting discussion on impedance, wattage current, and skin effect.

Other interesting chapters treat on the calculation of power in A. C. circuits; the theory and calculation of transformers and how they are connected in lighting and distribution circuits; alternating-current generators, their theory and construction; A. C. motors, including the synchronous motor and its characteristics; synchronous converters, their theoretical and practical operation; the generation of split-phase converters; A. C. to D. C. rectifiers of various types; including electrolytic and vacuum rectifiers, special regulators, measuring instruments for A. C. work, including synchroscopes and synchroscopes, and with numerous tables for the calculation of A. C. circuits for different frequencies and voltages. A clearly written handbook which explains in untechnical terms the principles of alternating currents for the practical electrical and student.

GERMAN ENVOYS TOLD TO SUR- RENDER, VIA RADIO.

A wireless message sent to the German delegates from German headquarters authorized them to sign the armistice.

The German commissioners remained up all night writing the final instructions. When the radio message arrived they hastened to a private train in which Marshal Foch was living and which formed his headquarters. Marshal Foch was asleep at the time. He was aroused. He received formal word that the Germans had come to terms.

The signatories affix their signature to the momentous document was Dr. Matthias Erzberger and Count von Galen. The German delegates followed. As they signed, one by one, they saluted, Marshal Foch and his aide-de-camp received considerable attention.

In the meantime, across the network of wires running from Marshal Foch's headquarters to Paris, the order for cessation of hostilities at 11 o'clock, Nov. 11th, began to be flashed up and down the far-flung western front, while from Paris and London the news started on its joyous trip around the world.
7 Big Volumes—Written by 27 Great Authorities—Yours for 7 Cents a Day

The hardest way to learn Electricity is through your own experience. The easiest way to learn is through the experience that others have paid for in time and money. Here in practical, easy-to-understand form, you get the benefit of what 27 greatest electrical authorities in America have taught all the world have learned, and you get this vast fund of experience in convenient book form, so that you can read and study in your own home in your spare time.

This is the greatest opportunity of your life to become an electrical engineer, sub-station operator, dynamo tender, or to get any one of the other big-pay jobs in the electrical field. For less than you spend for tobacco or movies, you can train yourself to step up to the jobs paying $2,500 to $3,000 a year.

AMATEURS! Get Ready for the Opening Day

**Practical Wireless Telegraphy**
By Elmer E. Bucher, Director of the Radio Laboratory In this book Bucher successfully explains in simple terms the principles of wireless telegraphy. He supplies the reader with a knowledge of fundamentals, construction, and practical operations. More than 60,000 copies of this book have already been sold. Price $2.00 postpaid.

**Radio Telegraphy**
By Alfred M. Goddard, Associate Director of Radio Laboratory In this book Bucher successfully explains in simple terms the principles of wireless telegraphy. He supplies the reader with a knowledge of fundamentals, construction, and practical operations. More than 60,000 copies of this book have already been sold. Price $2.00 postpaid.

**Vacuum Tubes in Wireless Communications**
By Elmer E. Bucher

An elementary text book for experimenters, students and operators. Covers all the material required for the FCC license examination with numerous diagrams and illustrations. Shows one hundred different circuits. Bound in full cloth. Price $1.75 postpaid.

**Practical Aviation Including Construction and Operation**
By J. Andrew White

This book is the story of the development of aviation, complete with diagrams and illustrations. Shows one hundred different circuits. Bound in full cloth. Price $1.75 postpaid.

These Text Books Have Been Used in Training Over 60,000 Men During the Past Year.

**WIRELESS AGE**
The only American magazine devoted exclusively to the wireless art. Covers all developments in the scientific, experimental and commercial fields. A magazine that keeps you posted on all the latest developments and gives you a broader working knowledge of all the art of wireless. Excellent, up-to-date and news feature articles with vivid illustrations and practical suggestions for red-blooded amateurs. Practical training courses by experts on wireless telegraphy, perforation, signaling, etc., in 16 issues. Up to the nearest newsstand and secure your copy, or we will mail it to you postpaid upon receipt of price, 16 copies, $2.50 per year.

**SPECIAL OFFER**
**THE WIRELESS PRESS, Inc.**
33 ELM STREET, NEW YORK CITY

Attractive circular fully describing our complete line of books, sent free upon request. Ask for Circular E.

**HOTEL MARTINIQUE**
BROADWAY, 33D STREET, NEW YORK
One Block from Pennsylvania Station
Equally Convenient for Amusements, Shopping or Business

157 Pleasant Rooms, with Private Bath, $2.50 PER DAY.

257 Excellent Rooms, with Private Bath, facing street, southern exposure, $3.00 PER DAY.

Also Attractive Rooms from $1.50.

The Restaurant Prices Are Most Moderate.

**WINTERTIME USES FOR THE ELECTRIC FAN.**
(Continued from page 619) be screwed down so as not to fall over and injure anyone.

Another illustration shows a very effective aid in the drying of milady's silk stockings, gloves and hair. The funnel "B" can be easily constructed of ordinary cardboard to fit the protective guard, and attached with wire. Or, it can be made a bit larger so as to slip a few inches over the protector, perforated at two or four places and tied at the back with string. Of course the width of the other end should be much narrower in order to produce the conical shape, as the sketch illustrates. A small piece of cardboard formed into a cylinder, and down or pasted together so as to exactly fit the end of the cone, is also fastened to it with wire. This is done by perforating both and sewing the wire from one hole to the other. The stock is then slit on and can be clamped down. (The clamps that are used on jam jars to make them air-tight would serve very nicely here.) Also books made of wire (picture wire would do), invisible hairpins, etc., can be affixed to the end of the funnel, on which handkerchiefs, stockings and gloves can be fastened. In the latter case it is not necessary to make the small cardboard attachment. It is readily understood that the forced air thru this funnel dries the articles in no time. Should it be inconvenient for you to make this funnel, the handkerchiefs, stockings, etc., can be attached to the protector itself by pins or hairpins. With this method it will take slightly longer for them to dry. Care should be taken to attach the articles before you set the fan going. Take them off after you have cut off the current with the snap switch and the fan has fully stopped. This precaution should be taken whether the electric fan is handled in any way.

Figure 15 shows a handy device that can be easily made from ordinary cardboard. A circle of tin is cut in the manner illustrated, allowance being made for small projections which are bent over and formed into hooks. It can be affixed to the protector guard with the projecting tabs. If the tin is not handy, cardboard will do just as well, except that the hooks must be made of wire or old hairpins. A good way to make these hooks is to thrust the hairpin thru the perforation, the two ends first, twisting them around at the other side of the perforation and then spreading them apart. About four cardboard tubes are inserted and sewn with wire as aforesaid, and a piece of cardboard large enough to fit the wire cage pro-
What does it feel to earn $1000 a week? How do I feel to have earned $200,000 in four years? I don't think I know the answer to these questions. But these are questions I feel I should be able to answer. Is it such a difficult task to tell the truth? I should like to answer these questions, and I should like to tell the truth.

I have been a journalist for many years, and I have never been afraid to express my opinions. I have never been afraid to say what I think. I have never been afraid to tell the truth. I have never been afraid to publish the truth.

THE GIFT OF GIFTS
FOR THOSE WHO
LOVE GOOD MUSIC

E. L. ELLIS
P. O. Box 882,
Milwaukee, Wis.

THE ELLIS "MUSIC MASTER" REPRODUCER

is the ideal Christmas gift for anyone who owns a phonograph or talking machine using disc records. This wonderful little reproducer bears the same relation to the reproduction of records as does Stradivarius to the making of violins. Both are masters.

There is as much difference in the effect of the Ellis Reproducer and ordinary reproducer as there is in the excellence between a genuine Stradivarius and a cheap factory made violin. As one user said: "Mr. Ellis, your reproducer is soulful and inspiring. The overtones are remarkable and wonderful, and the tone shading very beautiful." Ordinary reproducers, such as are supplied with all phonographs or talking machines, give a harsh, unpleasant sound and reproduce the human voice with a disagreeable nasal tint. The Ellis Music Master makes every note and tone as clear as a bell and reproduces it in its true tone quality. It is a marvelous little instrument that will please anyone who appreciates and can comprehend the difference between good and indifferent rendition of music. It is truly a "Music Master."

The Ellis "Music Master" is made for all machines using disc records. It is lighter than ordinary reproducers, therefore preserves and prolongs the life of records. The size is small, but the satisfaction great.

We today for circular E, which gives full details.

J. H. ELLIS.

Wireless Stations Will Shortly Re-open

Date, only, uncertain

We have a big stock of wireless instruments.

No. 11 is our latest catalog. No new price list.

Please do not write for catalog if you have No. 11. Paper costs three times as much as formerly.

Let the amateur without a catalog secure one. Write for prices in advance. Just now we have no price list, because the changes have been so frequent.

Send 8c in coins or stamps today for our No. 230 price No. 11 Electrical and Wireless Catalog. And wireless amateur will tell you if it is the catalog to have. You need, no others. Our catalog contains most everything in wireless worth while, and is a guarantee that the goods are dependable.

THE WILLIAM B. DUCK CO., 230-232 Superior St., Toledo, Ohio

He Learned
K'l' Shorthand
in 5 evenings - You can!

A VAUGHN M. AMER, the young man in the picture, did it. So have hundreds of others. He learned K'Shorthand in five evenings - and learned to transmit the entire system in five evenings; then sat and gave tests in a hall to a thousand students. E. K. Shortland is the man who invented it, and now a man has learned K'Shorthand and transmitted the entire system. What a short time it took to learn K'Shorthand!

Send for catalog.

30 Days Approval

We teach you the entire course on approval for 30 days with the understanding that you need not pay one cent if you do not learn. Prove it to yourself by trying two free lessons FREE. More Than a Text Book!

More than a Text Book!

GAS VERSUS ELECTRIC RANGE.

The gas range is better than half as efficient as the electric range. Recent tests show that the top surface of the electric range requires less than one-sixth the energy necessary to do the same work on the top surface of the gas range. The electric range oven requires but 23 per cent of the energy required at the top of the gas range. The electric oven is much more efficient in proportion than the top surface as compared with the oven and as compared with the entire range. Under actual household conditions the electric range requires about 55 per cent of the energy used by the gas range to do the same work.

NIKOLA TESLA AND HIS INVENTIONS.

(Continued from page 615)

either a dreamer or, worse yet, crazy. The fact is the world does not understand you because you live in the next century. Moses was used with great power, but the Bible teaches us that he was "heavy of tongue" and could not make himself understood. His brother therefore always spoke in his stead, according to the mannerism Moses had to say. Why not let the EXPERIMENTER be your brother? Why not let us translate your work into a language that the man in the street can readily understand? We have the knowledge and the technical training to do your inventions justice by means of great illustrations and written explanations. The public does not want patent drawings or patent language. It wants pictures and plain English. You are a great inventor, but your 21st Century training prevents you from making yourself understood to a 20th Century public. My plan is to run one of your inventions a month, in full, in English fully illustrated. That means that it will probably take over two years to deal with all of your more important inventions. At the end of this period the articles can be published in book form, a thing that does not exist at present. The plan is twofold. Success on such a large scale will at last understand the highly important work you have accomplished and will fully recognize you. Second, it will be of greater benefit to Science, to whom your inventions will then not be the sealed book they are today.

Knowing that Tesla had in the past continuously refused similar offers of dozens of great publishers of this country as abroad, I was not at all sanguine of my own plan. Great was my surprise therefore, that he not only gave his consent, but he actually agreed to prepare each invention, personally with the Editors' collaboration.

Dr. Tesla wants it expressly understood that he is undertaking this great work chiefly to educate the young generation. He felt that he could not possibly reach such a large electrically trained young mankind, save thru the medium of the ELECTRICAL EXPERIMENTER. With its circulation of about 100,000, all enthusiastic experimenters, Tesla feels that his greatest mission in life, namely, to assist our rising generation, will come near fulfillment.

Nikola Tesla's articles will therefore run serially every month in the ELECTRICAL EXPERIMENTER. The articles will be entitled: "My Inventions"—by Nikola Tesla. Every article will be entirely original; each will be illustrated with our own new illustrations and with such wash drawings as have been this journall so successful. The first article will appear in our February number.

We wish to congratulate EXPERIMENTER readers for having obtained for them probably the greatest technical news feature of a generation. I caution you: Expect much!

FARMERS AND ELECTRICITY.

Within the past three years the farmers of the United States have purchased one million automobiles and 100,000 tractors and innumerable pumping engines, and other devices run by electricity, according to wise published estimates. Farmers everywhere are rapidly advancing in the same direction, progress in labor-saving contrivances being phenomenal in this country. A motor does the churning; a motor runs the sewing machine and the washing machine. The rural telephone is invading country districts at the rate of many miles per day, and all farm machinery is being operated by the aid of tractors, which now haul the wagon and work the hay loader in the hay field. Next year, it is said, reapers and mowers in great numbers will be driven by tractors.

DEVICE FOR PROTECTING ELECTRIC MOTORS.

A motor protection system which, if claimed, does away with the trouble and expense of cleaning motors, has been devised and marketed. The usual type of installation, it is pointed out, in working out this system consists of casings which enclose each end of the motor and make it dust proof. A fan is attached to the end of the motor and air is drawn thru it which carries away the heat as fast as generated. Motor casings are provided with large doors to permit of a ready inspection of brushes, commutators, bearings, and the like. The dust separator is also provided with doors so that the screens can be readily removed. The equipment can be applied to motors with moving parts and requires a short time to install. Besides reducing the temperature and increasing the efficiency, the maker points out that the protection provided allows the carrying of a large overload without shortening the life of the motor and eliminates fire hazards.

DANIELS TELLS OF Foe RADIOS SCOUTS FOUND.

A telegram from Secretary of the Navy Daniels received by the Boy Scouts of America characterized them as "chivalrous young crusaders" because of their work during the war. It also disclosed that the Scouts, working on behalf of the Government, had discovered hundreds of illegal wireless plants.

Twenty-six of these plants were found in one day. A German alien, operating an underground radio station with a small New England river supplying the motive power, was taken into custody and interned. This plan was soon being exchanged by German Government agents between America and Berlin. Details of these scout activities are expected to be made public later.

“I Can Succeed!”

"What other men have done with the help of the International Correspondence Schools, I can do. If the I. C. S. have raised the salaries of other men, they can raise mine. If they have helped others to advance, they can help me. To me, I. C. S. means 'I CAN SUCCEED.'"

Make up your mind now that not another day shall pass until you have made your start toward success.

For 27 years men in offices, stores, shops, factories, mines, railroads, and in the Army and Navy have been winning promotion and increased salaries through the I. C. S. More than 100,000 men and women are getting ready right now with I. C. S. help for the bigger jobs ahead.

No matter where you live, the I. C. S. will come to you. No matter what your handicaps, or how small your means, we have a plan to meet your circumstances. No matter where you may choose to live, some one of the 288 I. C. S. Courses will suit your needs.

When everything has been made easy for you—when one of our top-flight instructors PAYS YOU—your home will bring you a bigger income, more comforts, more pleasures, that success means—can you let a single priceless hour of spare time go waste? Make your start today. This is all we ask. Without cost, without obligating yourself in any way, put it up to us to prove how we can help you. Just mark and mail this coupon.

energy received, even if it could be collected in its totality, is insufficent and would not actuate the most sensitive instrument known to be magnified many million times. The fact is that waves have no perceptible influence on a receiver if situated at a much smaller distance. It should be remembered, moreover, that since the first attempts the wave lengths have been increased until those advocated by me were adopted, in which this form of radiation has been reduced to one-billionth.

When a circuit, connected to ground and to an elevated capacity oscillates, two effects separate and distinct are produced; Hertz waves are radiated in a direction at right angles to the axis of symmetry of the conductor, and simultaneously a current is passed through the earth. The former propagates with the speed of light, the latter with a velocity proportional to the cosecant of an angle which from the origin to the opposite point of the globe varies from zero to the limit of 30°. Expressed in words, at the start the speed is infinite and diminishes, first rapidly and then slowly until a quadrant is traversed when the current proceeds with the speed of light. It is seen that region on the velocity gradually increases, becoming infinite at the opposite point of the globe. In a letter to me in April, 1905, I have summed up this law of propagation in the statement that the projections of all half waves on the axis of symmetry of movement are equal, which means that the successive half waves, though of different length, cover exactly the same area. In the near future many wonderful results will be obtained by taking advantage of this fact.

There is a vast difference between these two forms of waves as far as the bearing on the transmission. The Hertz waves represent energy which is radiated and unrecoverable. The current energy, on the other hand, is preserved and can be recovered theoretically, at least, in its entirety. If the experts will free themselves from the illusions under which they are laboring, they will find that to overcome static disturbances all that is needed is a properly constructed transmitter, and receiver without any additional devices or preventives. I have however devised schemes of apparatus eliminating statics even in the present defective wireless installations where they are not magnified and multiplied. Such a form of instrument which I have used successfully is shown in the annexed photograph. These phenomena have been studied by me for a number of years and I have found that there are a number of different causes tending to intensify them, and in due course I shall give a full description of the various improvements I have made, in the ELECTRICAL EXPERIMENTER. For the present I would only point out that in order to perfectly eliminate the static interference, it is indispensable to redesign the whole wireless apparatus as now employed. The sooner this is understood the better will be for the further evolution of the Art.

A means of making use of the electric magnet under water has been devised in Japan, and it promises to be of great assistance in locating submerged bodies of which salvage operations on a big scale are expected after the war.

With the aid of special oxygen masks airplane experts believe that air fighters will be able to carry on battles five miles above the earth.
NEW BATTERY CHARGER SIMPLICITY ITSELF.

For the Garage Man going into Battery or Service work on an ample scale, or for the Garage that has outgrown its present equipment, an Ohio concern has brought out a new 32 battery capacity Charging Outfit shown herewith.

With this outfit batteries in all stages of charge can be handled with the four charging lines provided, caring for eight batteries in each line. Batteries requiring different charging rates can be handled according to their individual needs, due to the ample output of the machine. Different voltage batteries can also be charged in the same line, due to the automatic voltage control of the Generator.

With this outfit, battery charging work is claimed to be very profitable, and the makers state they have designed the outfit wholly with the idea of bringing the Garage the largest profits possible from this class of work.

DO YOU ASSOCIATE COLORS WITH FIGURES?

The recent letter to Science from David St. Jordan led to my attention a fact which I did not know before, says Arthur Bessey Smith, the well-known telephone engineer, in that journal. On mentioning it to my laboratory assistant, Mr. Herbert Edward Clapham, he said that he, too, associated colors with the letters of the alphabet but not with all, and that figures were also associated with colors. At my request he wrote out the following list:

A gray  O black  1 white
B light red  P brown  2 red
C black  Q light red  3 light red
d  pink  R k  4 gray
E scarlet  S white  5 white
F pink  T red  6 white
G gold  U golden brown  7 golden
H yellow  V gray  8 brown
I white  W v  9 red
J white  X yellow  10 black
K  Y white  11 red
L  Z  12 red
M olive green
N olive green
O

Altho I have never associated colors with letters or figures from my earliest recollection I have always thought of letters and of figures arranged in certain relative positions. The origin of this I do not know. It might have been something in the presentation of these things by my first teacher, or the manner in which little wooden sticks were laid out on my desk in high school and college work. These little sticks, each about 3 mm. in diameter and 20 mm. long, had been split out of pine for me by my father.

Which Job Can You Fill?

Which one of them could you fill? If you haven't the knowledge necessary to break into the big-pay class, decide to get that knowledge NOW! Any of the books listed below will quickly fit you for a well-paid job—at home in your spare time.

These books were written by experts in plain, everyday language. They are free from puzzling technical terms. Numerous illustrations, diagrams and tables make difficult points as simple as A-B-C. They are handsomely bound in half or full leather (except Law and Practice, which is bound in law buckram) and stamped in gold. Fill out the coupon.

Automobile Engineering

Five volumes, 2200 pages and 2300 illustrations. Prepares for Illinois Institute of Technology, University of Utah, Brown University, Caltech, Fordham University, Washington University, University of Minnesota, Columbia University, Yale University, Engineering Degree. Regular price, $25.00. Special price, $23.00.

Machine Shop Practice

Six volumes, 2200 pages and 2000 illustrations. Prepares for Bushwick Institute, textile, leather, etc. Descriptive literature. Five galleys, $25.00. Special price, $23.00.

Sanitary, Heating and Ventilating Engineering

Three volumes, 1100 pages and more than 1600 illustrations. Prepares for Howard University, Engineering Degree. Heating and Ventilating Engineer, Master Plumber. Register price, $25.00. Special price, $22.00.

Law and Practice

With Reading Course In 2 bound pamphlets. Thoroughly practical, written for the Attorney, Barrister at Law and Bar examinations. 10000 copies sold. Regular price, $25.00. Special price, $22.00.

Practical Accounting

Four volumes, 1200 pages and 800 illustrations, plates and diagrams. U. S. A. liabilities and practical problems. Prepares for Accounting, Bookkeeper or Cost Clerk. Register price, $25.00. Special price, $22.00.

Carpentry and Joinery

Five volumes, 2200 pages and 2300 illustrations. Prepares for Contractor, Building Superintendent, Carpenter. Foreman. Register price, $25.00. Special price, $23.00.

Civil Engineering

Nine volumes, 2200 pages and 2200 illustrations, plates and diagrams. Prepares for Civil Engineer, Structural Engineer, Triangulation Engineer, Estimator, Design or Chief Draftsmen. Regular price, $46.00. Special price, $28.00.

Electrical Engineering

Seven volumes, 2200 pages and 2200 illustrations, plates and diagrams. Prepares for Electrical Engineer, Power Plant Superintendent, Substation Operator. Regular price, $25.00. Special price, $13.00.

Accountancy and Business Management

Ten volumes, 2200 pages and 2200 illustrations, plates and diagrams. Prepares for Certified Public Accountant, Assistant. Register price, $25.00. Special price, $23.00.

One Week Free Trial

We'll gladly send you any set for seven days' examination. Don't send us a penny; just pay the small shipping charge when the books arrive. Examine them carefully—use them at your work for an entire week. At the end of that time, if you feel they aren't worth far more than we ask, return them at our expense. If you keep them, pay them the bargain price on the easy terms explained below.

CHEMISTRY!

We present herewith to our friends our new E. I. Co. Chemical Laboratory which contains real chemicals and apparaata to perform real chemical experiments. This outfit is not a toy, but put up merely to amuse, but a practical laboratory set, with all the chemicals, apparaata and reagents necessary to perform real work and to teach the beginner all the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

44 Chemicals
17 Apparata
1 Instruction Book with 100 Experiments

PRICE
$5.00

Shipping
Weight 10 lbs
CAN BE SHIPPED
BY EXPRESS ONLY

THE E. I. Co. CHEMICAL LABORATORY
DESCRIPTION OF THE OUTFIT

It contains the following 44 chemicals:

Ammonium Chloride  Brimstone  Ferrous Sulphate  Iron Chloride
Alum  Iron Oxide  Nickel Sulphate  Calcium Oxide
Antimony  Sulphate of Zinc  Sodium Sulphate  Stannous Chloride
Boracic Acid  Magnesia Carbonate  Zinc Sulphate  Nickel Chloride
Charcoal  Zinc Metallic  Ammonium Sulphate  Hydrochloric Acid
Sodium Nitrate  Sodium Bicarbonate  Ammonium Carbonate  Sulphuric Acid
Sodium Carbonate  Sodium Carbonate  Ammonium Aque  Iodine
Sodium Borate  Sodium Sulphate  Calcium Chloride  Mercury, Metallic
Sodium Sulphite  Sodium Chloride  Chloride of Zinc  Tin, Metallic
Manganese Dioxide  Calcium Sulphate  Copper Sulphate  Littmus Paper
Oxalic Acid  Barium Chloride  Glycerol  Ferrous Sulphide

The following apparaata are furnished:

Six Assorted Test-Tubes  One Test-Tube Holder  Glass tubing
One Standard Washbottle  Ten Sheets of Filter Paper  One book containing Treatise on
One Conical Glass Measure  One Glass Dropper  Elementary Chemistry and 100
One Erlenmeyer Flask  One Spoon Measure  Chemical Experiments to be performed with this outfit.
One Glass Funnel  One Delivery Tube

THE ELECTRO IMPORTING Co., NEW YORK.
SEE OUR FULL PAGE AD ON PAGE 679 FOR FREE CYCLOPEDIA

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
In this Department we publish such matters as are of interest to inventors and particularly to those who wish to know as to certain Patent Phases cannot be answered by mail free of charge. Such inquiries are published here for the benefit of all readers. If the idea is thought to be of importance, we make it a rule not to divulge all details, in order to protect the inventor as far as it is possible to do so.

So far has been desired by mail a nominal charge of $1.00 is made for each question. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

Readers' attention is called to the fact that due to the great amount of letters to this department it is quite impossible to answer them all thru these columns. The inquiries answered in this way in large number each weekly, and if readers wish speedy service they should carefully note the announcement appearing in the preceding paragraphs.

**Code Practice Instrument.**

(289) Geo. R. Griffin, Troy, N. Y., writes: "I have noticed in the November number of the Electrical Engineer an article by A. L. Kopp, New Middletown, Ind., called 'Code Practice.' I have found it with me. I have an idea which might be of value to Mr. Kopp's instrument, and am enclosing a copy of same with the request to publish the device at your convenience."

Mr. Griffin suggests putting the lamp of the practice outfit right on the key lever as shown in our illustration. By this means the bulb is screwed in the socket made for that purpose on the lever of the key. This has a tendency to light the bulb on the downward stroke instead of the upward stroke.

A. This strikes us as a good solution of Mr. Kopp's problem, and of course it this case Mr. Griffin and Mr. Kopp should really be joint inventors in any further patent action. The solution seems satisfactory.

**Invisible Periscope.**

(292) Mr. Geo. Utz, Newark, N. J., submits an idea of what he calls "invisible periscope". The periscope tube is to be surrounded with a heavy glass tube, while the space between the periscope tube and glass tube is to be filled with sea water. The periscope tube is to be painted to match the sea water. Our advice is asked.

A. While an ingenious idea, this is not different from many other similar devices which have been suggested in the past. The trouble is that it is not the periscope itself which makes the trouble, but the V-shaped wave of curried water which is left behind as the submarine speeds thru the water. The periscope itself can be and has been camouflaged in the past in such a way as to render it almost invisible within a hundred yards. Of course, this is all right while the submarine is not moving, but once it starts moving, the periscope immediately leaves a tell-tale wake behind it.

**Ice-Cream Cone.**

(293) Gardner W. Wymond, Pittsburgh, Pa., says: "I would like to submit a plan for a paper ice-cream cone that is to take the place of cake cones now in use, as I understand there is a shortage of the latter; the plan is to make a cone of the same shape as cake cones out of fairly heavy wax paper, the latter to be formed like a paper pencil as the cone is eaten away." Our advice is asked on this point.

A. We are afraid that while it looks feasible on paper, it would not work out in practise for the reason that it would be too expensive to maintain the proper motion to thus unroll the wax paper, which surely would splash melted cream over the eater.

**Diving Mine.**

(290) W. F. Ash, Jacksonville, Fla., writes: "Has there been a patent issued for a 'diving mine'—power to be furnished by small motor or clockwork which will take in water in the surface of the sea, which will cause it to sink to the mine taken over by, and after it has gone down to about fifty feet, it will throw out water, and thus cause it to rise in time to blow a Liberty ship up."

A. To our knowledge there has never been anything of this kind invented, and we have never seen any reference to it. We think this device of this kind is more or less impossible.

**Safety Soap.**

(291) W. L. McGowan, Holdenville, Okla., writes: "To your knowledge has there been any device patented for preventing soap from being stolen or destroyed from public places? Furthermore, what do you know of such a device. The device which I speak of is composed of a flat steel utensil, runs kind of inverted before, and is fastened by chain at one end and small lock on the other. Any information that you can give me concerning this matter will be greatly appreciated."

A. This is a very old idea, and one which we have seen in actual use in hotel and public wash-rooms years and years ago. There is nothing novel about this, and nearly all of these devices have been superseded by automatic soap dispensing machines, such as liquid soap, where you only have to press a button to get a thimblefull of liquid soap in your band, or the other device whereby you have to handle which puts soap shavings into your hand.

**Improved Code Practice Instrument.**

**PATENTS**

**With a Sketch, Battle-stolen a Ship Kopp's Light**

Don't Lose Your Rights

Before disclosing your invention to anyone send for blank form "Evidence of Conception" to be signed and witnessed. A sample form together with printed instructions will show you just how to work up your evidence and establish your rights before filing application for patent. As registered patent attorneys we represent hundreds of inventors all over the U. S. and Canada in the advancement of inventions. Our schedule of fees will be found reasonable. The form "Evidence of Conception," sample, instructions relating to obtaining of patent and schedule of fees sent upon request. Ask for them—a post card will do.

255 OURAY BLDG., WASHINGTON, D. C.
ELECTRICAL EXPERIMENTER

Electric Radiator.

(294) Earl F. Hobbs, St. Louis, Mo., has an idea of a hot water radiator, electrically heated with expression of the most resounding assurance that it could be moved from one location to another and from room to room could be made equal to 34 inch pipe with about a 500 watt element made of copper. The radiator has a medium and a low point.

A. There is nothing fundamentally new in electrically heated water radiators as our correspondent suggests in his letter. We have in the Electra-ised systems often described numerous electrically heated radiators of this sort.

Poison Shell.

(295) Joseph Vierthaler, Philadelphia, Pa., submits description and device of a poison shell which comprises an ordinary shell with a hollow center. Poisoned gas is enclosed in the shell, the trigger is put in the shell when manufactured. Our advice is asked.

A. There is nothing new at all about this, and the present gas shells as have been used by the Germans as well as all the Allies and the United States are made along precisely this plan.

Fan Guard.

(296) Ladimir H. Sybrock, Cleveland, Ohio, writes, "As editor of the 'Patent Advice' I would appreciate your advice on the following: Would it be advisable to employ a guard for a small special electric fan having blades but 3" long? The guard if employed must be disasutable. I have been advised to use a 'sand guard.' Could you give me details regarding this or any other disasutable guard?"

A. We see nothing fundamentally difficult in making a detachable guard fan to work in conjunction with a small fan. It seems that any material, shape, or a clever experimenter ought to be able to devise such a guard, which seems very satisfactory, and do not know, however, what you mean by sand guard. We do not know in what this refers.

Telephone Receiver.

(297) Frank M. Harrington, Fulton, Ill., sends in a sketch of a telephone receiver which we reproduce herewith. The device employs two lobes having a central opening which are to pull in two soft iron needles 1/16 inch in diameter attached to the diaphragm as shown. We are asked if this design is good, whether the telephone is sensitive and whether the device has ever been tried before.

A. This is similar to an idea described some time ago in these columns. Right here we want to send the telephone receiver as a rule — with very few exceptions — which has its diaphragm weighed so as to interfere with the free vibration of the latter, usually is less sensitive than the diaphragms which swing free. We are quite convinced that the construction shown by

ONE READER'S EXPERIENCE
WITH DR. ABRAMS' THOUGHT TRANSFERENCE THEORY.

As our reader's will recollect, we suggested in the September issue in connection with the article therein entitled "Popular Demonstration of Thought Transference and Other Phenomena," by Dr. Albert Abrams, that they write to us as to what success they have attained in conducting any of the demonstrations outlined by Dr. Abrams in this little known field of science, and we are pleased to give herewith the views of Mr. J. W. White of Brooklyn, N. Y.
Mr. White having witnessed a number of these tests conducted by Dr. Abrams personally, and visiting San Francisco several years ago. Furthermore, Mr. White, who is in the electrical business in New York City, and a thorough worker, is a student of electrical and allied matters, had the satisfaction of taking part in some of the experiments in Dr. Abrams' laboratory, and his views are given below, those of an unprejudiced and unbiased student.

Many people undoubtedly who have read the article in question have tried, unsuccessfully perhaps, to obtain results by current methods, according to the theory of Dr. Abrams, such as for instance where the "perception" or person interpreting the thought transmitted or emitted, is connected to another person or body which forms the exciting point in the unipolar (single wire) circuit.

Here, for example, is what Mr. White experienced, and certainly it is well to remember that the high professional standing of Dr. Abrams in the medical and scientific fields precludes all doubt of any fake results. He, however, had reached a point where the phenomena, however little we may as yet know as to the exact mode in which such phenomena take place. First Dr. Abrams placed Mr. White in a separate laboratory room and gave him a permanent steel bar magnet, which as we all know has a North and a South pole. At the alternate ends the Doctor instructed Mr. White to present either magnet pole as he might elect to the steam radiator in the room, when he would be able to tell by a sensitive instrument laboratory just which end of the magnet he had presented. According to the theory of Dr. Abrams, the action here was as follows: That by charges from the magnet, even when held a short distance from the radiator, charged the metal piping system, and this particular discharge past along the radiator and metal piping to the laboratory where an instrument or a human subject for the instrument was connected by one wire to another radiator connected to the system. In this connection it is interesting to note that Dr. Abrams usually prefers to employ some delicate human reflex, such as the heart or stomach reflex, for indicating when one of these extremely minute electric currents arise, and which agents he, among many thousand times more sensitive to minute currents than are the most delicate scientific instruments such as galvanometers, etc. To sum up, as Mr. White was able to tell quickly just which magnet pole Mr. White had presented to the radiator, not making a single miss in twenty tests.

One of the most astounding phases of this particular excitement was when the Doctor informed Mr. White that it was not at all necessary that he present the magnet to the radiator, so as either to touch it or approach close up to it, but that he could determine which pole of the magnet the investigator was thinking of if he would but lay it on the floor and concentrate his mind as if he were to touch it directly.

If you like electricity and are electrically inclined—there is where you will be most successful; for electricity is your calling. And the great field of electricity, with its superior advantages, opportunities and possibilities is calling to you now. Answer that call by obtaining the thorough, complete and practical electrical education, training and development this school offers. You will need ability because only electrical men with ability are chosen for the high electrical places. But don't just work at electricity, learn electricity. Don't just be ambitious. Be determined to succeed as one of the thorough efficient electrical men so anxiously sought. Enroll with this school now—don't wait and waste your time.

BECAUSE OF THE

SHORTAGE OF CRUDE RUBBER

You can SAVE $10.00 on our Standard VIOLET-RAY MACHINE

Being afraid that we could not get delivery on hard rubber used for the outside casing of the Violetta machine, we made 500 of these in wood. Now these machines are exactly alike in construction and workmanship as our latest model standard machine which costs $35.00.

The only difference being that instead of using hard rubber for the casing, wood is used, but it is finished in a beautiful black piano finish, and the difference is hardly noticeable.

Now we cannot send these out as standard machines, so are placing them in a special lot at $15.00 an actual saving to you of $10.00. Besides we guarantee these machines to be new. The Outfit includes the generator, one general electrode and a handsome carrying case.

How to secure one of these machines?

Send only one dollar to pay express charges and we shall send you one of these instruments by express for your examination. This amount will be deducted from total cost of machine. You need not accept if not satisfactory.

Send at once for this the only lot we have of these machines and prices on the standard machine will advance in 30 days.

BROWNING GUN SUCCESSFUL IN AIRPLANE PROPELLER TEST.

The Browning machine gun has successfully undergone a test to determine its value for use with aircraft. This is one of the three types of machine guns with which the rate of fire can be synchronized, so that the gun can be fired by the pilot of a combat plane thru the revolving blades. It was found necessary to aim the machine gun by steaming the plane directly at the target. The direction of the plane gives direction to the fire and the pilot can control the machine gun while controlling the plane.

Airplane propellers revolve at 800 to 2,000 revolutions per minute. The machine gun is connected with the airplane engine by a mechanical, hydraulic or electrical device, and impulses from the crank shaft are transmitted to the machine gun. The rate of fire of the machine gun is constant, and its fire is synchronized with the revolving propeller blades by "wasting" or adjusting certain percentage of the impulses from the airplane and by having the remaining impulses trip the trigger. These impulses fire just at the fraction of a second when the propeller blades are clear of the line of fire.

The pilot operates the gun by means of a lever which allows the impulses to trip the trigger. It has occurred in practice that as many as 15 shots have hit the propeller without putting the plane out of commission.

FAKE ELECTRIC PISTOL TO SCARE THIEVES.

A new electric flashlight pistol of French invention is said to be in existence, not only displays a bright light when the trigger is pulled, but also makes a noise like a real weapon as well.
PHILA. TO BE BIGGEST ELECTRICAL CENTER.

Philadephia is to be made the largest electrical center in the world after the declaration of peace, according to plans now being perfected by the Westinghouse engineers.

Experimental Chemistry

(Continued from page 639)

Chemical Properties.

1. Yellow phosphorous possesses great affinity for many of the elements, uniting with all directly, except nitrogen and carbon. With Bromin and Sulfur it reacts violently. Characteristic is its affinity for Oxygen. When exposed to the air at 40° C. or at a lower temperature, if in a finely divided state, ignition takes place, burning to Phosphoric acid, according to the supply of oxygen present.

2. It is luminiscent in the dark, even the minute particles adhering to the fingers on handling matches.

3. Because of its great affinity for oxygen, phosphorous is an energetic reduc- ing agent. Sulfuric acid is reduced to Sul- fur diox. Nitric Acid is decolored with explosive force. The elements of the metals are reduced to their metals and phosphides, thus silver nitrat is reduced to Silver and AgP,

Red Phosphorous. Properties. 1. This is an allotropic modification, and possesses properties essentially different from the yellow variety. It forms a dark red to redish-brown powder, which is insoluble in carbon disulphide and all other solvents. It does not Phosphoresce, and is stable in the air. It does not ignite when quickly heated above 200° C. the vapors change to those of yellow phosphorous. This variety is prepared by heating the yellow phosphorous to 300° C. in closed, air-tight vessels, and after the conversion, the product is then treated with carbon disulphide to remove any of the unchanged phosphorous. If a little iodin be added, this change will take place below 200° C.

Scarcet Phosphorous. Properties. This is another modification, being obtained by boiling a solution of phosphorous in phosphorous tribromid. It resembles the red variety except that it is more active, reducing the copper, with the alcalies, it yields phosphin [PH₃] and a hyposulphite.

Metallic Phosphorous. Properties. This form is obtained by heating the yellow phosphorous at 600° to 700° C. from air to 530° C. It thus forms black metallic shining crystals, which are less active than the red variety.

Luminescence or Phosphorescence.

If a match is scratched in a dark room a faint line of light may be observed as the minute particles of phosphorous which are left glow and oxidize. The same thing occurs if an oxygen lamp is exposed in darkness, and the phenomenon is called PHOSPHORESCENCE. It is due to slow combustion (or oxidation). Substances rubbed with phosphorous give the same effect.

Many other minerals and chemical com- pounds have the same property; emit light in darkness, and some of these form the basis of the so-called luminous paints. The sul- fides of Barium, BaS, BaS₂, BaS₃, etc., are examples.

Some animals, as fireflies, glowworms, etc., cetera, emit a light from a certain part of the body, without heat above that of the rest of the body. In Cuba, a species of luminiscent insect is bottled up and used sometimes for lighting purposes, about the same manner as the glow-worm.

The light is apparently due to an oxidation of animal tissue which is under the control of the insect. To produce the same light by the oxidation of gas, it is necessary to have a temperature of about 2000° F. and 99% of the energy of the flame is lost, while these need but a 5% of the energy of oxidation, without any apparent rise in temperature. The animal supplies its own light.

Uses.

Phosphorous is used mostly in the manufac- ture of matches. A kilogram (2.2 lbs.) of it will tip about two million matches. It is also used to some extent for medicinal purposes.

Matches.

The making of matches after the splints are prepared includes two processes. First, one end is dipped into melted sulfur, some of which adheres to the wood. Second, it is dipped in a red mixture of phosphorous, an oxidizing agent, and glue. A little coloring matter is quite frequently added. The oxidizing agent may be Potas- sium chlorat [in which case the wood has a burn and burns vigorously on being scratched], potassium nitrat, Manganese dioxid, or red lead [Pb₃O₄]. This result is accomplished by pressing the end on a slate slab covered with the paste. Sulfur is necessary, as the heat liberated in the burning of phosphorous is not enough to set the wood on fire, and a coating of P₂O₅ forms over it. Sometimes paraffin is utilized in place of the sulfur. The well-known Swedish [or Safety] match head does not contain phos- phorous, but consists of a mixture of potas- sium chlorat and dichromat with red oxide lead and antimony sulfid. They are ignited by scratching them on the prepared surface of the box, which is essentially a mixture of red phosphorous, antimony sul- fid and powdered silica. A machine has been constructed to cut the splints, tip the matches, and dry and pack them in boxes, all four processes being automatic and con- tinuous, besides eliminating the poisonous fumes.

A Burning Match.

Whenever one ignites so simple and com- mon a thing as an ordinary match, little does he realize the miracle taking place. One of the most wonderful and complicated of chemical experiments. The mere fact that fire could be obtained by simply scratching the end of a stick was regarded less than three-quarters of a century ago, as a truly remarkable triumph of science.
chlorate, then potassium chloride is left. The heat of the burning phosphorus is enough to set fire to the sulfur, which unites with the oxygen of the air to form sulfur dioxide, and this in turn sets the wood on fire.

The reactions of a burning match are many. Try and complete the following and explain from what each comes. The next time you strike a match you will probably stop to think of the complicated change which takes place. This only goes to illustrate that many seemingly unimportant operations made during our daily routines may, if carefully analyzed, show the complicated changes which take place unobserved.

1. KClO₃ + S → 3ClO₂ + SO₂
2. K₂S + SO₂ → 2K₂SO₃
3. 2F₂ + 3Cl₂ → 2ClF₃ + FCl₃
4. K₂S + SO₃ → 2K₂SO₄
5. 2P + 3H₂O → P₂O₃ + 2H₂
6. P₂O₅ + 3H₂O → 2H₃PO₄
7. 6HCl + 6O₂ → 6HClO₃

Phosphates.

Wheat contains compounds of phosphorus, and most food plants in order to come to fruition must take phosphates from the soil in which they grow. The phosphates must be soluble, so that, as the rain dissolves it, it can be absorbed by the roots and circulated in the sap of the plant. Soils have to be renewed or fertilized, and fertilizers contain, among other things, the soluble phosphate H₂Ca₃[PO₄]₂, made according to the first step in reducing the element. This is absorbed, transformed, and assimilated by the plant, especially the fruit.

Animals eat the fruit, and thus the compounds of phosphorus are again transposed, circulated in the system, and deposited wherever needed, as in the bones and nervous tissues, and especially in the brain. Man feeds upon either plant or animal, and thus obtains phosphorus. From the human system it is excreted by means of the blood and kidneys, as phosphates and macroscopic salt (H₂Na₃PO₄). When the brain is hard worked, more usual is excreted;—in fact, there seems to be a direct ratio between the amount excreted and the vigor of brain action, as the intellectual effort was attended by the combustion of phosphorus. A simple test of the urine will demonstrate this. At the start of the day or at the end, or under normal conditions, appear clear yellow. Examine a sample of urine from the same subject taken after a hard day's brain work, and you will see bundles of very little white specks floating about. This represents the phosphates, and while the laboring brain is in search of a nerve impulse, if any, of these suspended phosphates in the urine at the end of a working day, the brain worker will invariably manifest this condition regularly. To clear the urine in order to test it for any solids or sediment, add a little nitric acid. It will clear up perfectly if the urine is normal.

Experiment No. 147.

Place about 12 heads of ordinary (not safety) matches in a flask, as shown in Fig. 155. Have this flask (1) about half filled with water. Proceed to distill the same by applying the Bunsen burner under the flask, taking care that the action does not become too violent.

If this experiment is performed in a darkened room a ring of greenish light appears at the level of the water in the condenser, where the sulfuric acid is. After a short time little colorless spheres of a waxy solid collect under the water in the second flask, which acts as a receiver for the drippings from the condenser. If the water is poured away, this solid begins to give off a white smoke, and is luminous in the dark.

POPULAR ASTRONOMY.
(Continued from page 621)

There is the question of life. From the habitability of the nearest satellites of Jupiter, if they may, on the other, hand, be barren, lifeless worlds, such as Mercury and the Moon. Their great distance from the highly heated interior and spread out into belts parallel to the equator and in the direction of the planet's rotation. From its nearest satellite all the interesting changes of color and form that constantly take place in the atmosphere of this great globe could be observed in great detail.

Diagram I.—Showing the Relative Sizes of the Four Moons of Jupiter, Io, Europa, Ganymede and Callisto, or Satellites I, II, III and IV respectively, and the Moon and Terrestrial Planets. Distance from C to S is the Distance from the Center to the Surface of Jupiter. So If All the Satellites of the Planet and the Terrestrial Planets and Their Combined Diameters Would Fall Short of the Surface of the Planet by a Distance About Equal to the Diameter of the Earth.

The high percentage of light and heat that Jupiter reflects from the sun to its nearer satellites would make it a secondary sun to them of tremendous size but feeble strength. As seen from the nearest moon the other three major moons of Jupiter present all the phases of our own moon in rapid succession, due to their constant changing positions with reference to the sun. The five small moons, discovered in modern times, are so minute that they are simply star-like points of light even when viewed from the other moons of Jupiter.

When nearest each other some of the moons appear even larger than our own moon does to us, but when approaching opposite sides of the planet their disks rapidly diminish in size so they never appear as small as the far distant sun nearly five hundred million miles away whose apparent diameter is less than one-fifth that of the full moon.

To keep track of the rapidly changing positions and various phases of the moons of Jupiter as seen from any one of them,

Diagram II.—Orbits of the Four Old Satellites of Jupiter, and Saturn V, Not First To Be Discovered of the New Moons. Satellites VI and VII Are Nearly Seven Times More Distant and Satellites VIII and IX Nearly Fourteen Times More Distant Than Satellite IV. The Period of Revolution of Satellite V Is 12 Hours and of Satellite IX 3 Years. Scale 6 Cm. = 200,000 Miles.

You know by mentioning the "Electrical Experimenter" when writing to advertisers.
as well as the rapid apparent motion of the planet thrush the sky due to the revolutions of the satellite itself, would be a troublesome task for an astronomer stationed on one of these far distant worlds. It would be a common sight to see in the sky at one time, however, the planet itself, and one, two, or three moons. Seen from the moons of Jupiter the constellation would appear as they do to us on earth for a slight change of five hundred million miles, more or less, is trivial when one is measuring the relative distances of the stars. Observations of the relative stars from the great moon of Jupiter would be attended with difficulties at times, however, since reflected sunlight from a body 120,000,000 miles distant would be extremely troublesome, especially were the phases of the planet near that of the full moon. Even from the fourth or most distant of the major satellites the planet would subtend an angle of nearly five degrees. Occultations of the stars would be many and frequent as the huge planet globes swiftly drift through the heavens. Many a moonlight night would appear almost as day owing to the presence of the enormous bodies reflected from the light of Jupiter and occasionally two or three moons in addition. Only the brightest stars would be seen under such circumstances. When, however, the small worlds passed in shadow of the great mother planet and not only the light of the sun but also the reflected light of Jupiter disappears for many minutes the stars shine forth in all their glory there as here. In the sky would appear, possibly, some of the larger moons feebly shining by the reflected light of the far distant sun. Saturn also might be visible, but beautiful Venus and ruddy Mars would fail to appear. Tiny bodies, mere specks of light at this distance, they are lost to view in the glare of the sun.

(The next installment will appear in an early issue.)

ELECTRIC DEATH TRAPS IN HUN'S RETREAT.

(Continued from page 608)

to blow the cave to pieces, and which was connected up with an electric device to the—well, to think of it! I reach toward the Rhine as the Boches not only hope to gas their victims, but to kill them as well, one way or the other.

The daily press had considered to say in the later month of December concerning the many devilish and ingenious delayed time-fuse bombs which were left behind in many of the towns and cities of northern France. Once as the Rhine army was being driven toward the Rhine by General Foch's victorious armies. One of the simple devices of this nature, which blow up buildings, etc., a considerable length of time after the Hun's had retreated from a certain locality, is shown in Fig. 10. It comprised nothing more than a tank similar to those used on all modern plumbing for flushing purposes. As soon as it started to rain, such weather being frequent in northern France, the tank filled up and caused the float to rise. When the float ball reached its uppermost permit it closed such an electric circuit which set off the fuses running inside the building, to a heavy charge of explosive, with results that can be better imagined than described. These cowardly and devilish tricks are not only blame and harmless when you read them "Over Here."—imagine what havoc and untold death that have spread. Of course, it often happened that troops had occupied a town for several days before some of these delayed time fuses functioned at unexpected moments!

INDEX TO

ELECTRICAL EXPERIMENTER

FOR VOLUME 1, 2, 3, 4, 5

This index contains 24 pages and shows every article of the magazine which has been published since the inception of the magazine up to including April, 1918.

It is absolutely invaluable to anybody interested in any kind of electrical research work. With it everything previously known in the advancement of electrical science during the last five years can be readily found.

STOP SNUFFLING!

Sneezing, hawking, spitting and coughing. Why do you have catarrh anyway? You were not born with catarrh—you contracted it. This is often, unwholesome, discourage complaint that afflicted it upon you and grew. Nature is trying to prevent more serious consequences due to the congestion in your body, finds an outlet for the accumulated waste, by way of catarrh. You cannot cure it, for it is going on everywhere, but you may stop it by going—sprays, lotions, snuffing powders, drugs and medicines won’t stop it. You know catarrh leads to other troubles—loss of strength, lung, stomach, intestines—all become affected. You can never enjoy good health, if you have catarrh; you won’t be content in the一件事 as long as you have catarrh, and it detains from your powers to be hawking and snuffling again.

Build Yourself Up|

Be Clean—Wholesome—Healthy—Vigir. Go at it the right way. Nature’s way: no drugs, no medicines, and you banish catarrh from your system. Let me show you how, by my method of health developing body developed called

STRONGFIST

In practice, the health of our times, gives brown and muscle. It invigorates heart action, strengthens kidneys, and makes you bow down more in natural strength, it makes every organ in your body pride to health. In fact, it gives new life to every system of the body. It gives a life to the heart, lungs, stomach, kidneys, bladder, bowels, and all sorts and kinds of ailments and disorders.

The proper method of doing this is to mix the powder in the proper way and take it in the resolve method. The powder consists of

EXPERIMENTAL MECHANICS.
(Continued from page 638)

secured to the saddle. The circle should be marked with a sharp scriber where the boring is to be done, also its final diameter.

By bringing the work forward to the sharp point of the scriber which is attached to the boring rod, and revolving the boring rod, the scriber making the proper mark, this will aid in boring the hole to the proper diameter. At the same time you can see whether the hole is secured to the saddle with respect to the central line of the cutting tool, also live and dead centers. The cutting tool is held on block T. H., or tool holder, and is secured to the boring rod by a set screw. The boring rod is run between the centers and firmly attached to the line scribed by means of a lathe dog D to the face plate.

The novice can construct a very simple form of boring cutter, such as that shown in Fig. 4. A boxiron rod, B. R., which may be of any desired length, depending on the character of the work. The rod should be made of tool steel, having a diameter large enough to prevent its springing or bending when used in boring. The longer the rod, the greater the chance of sprunging, and, therefore, the longer the rod makes the rod as short as possible. A one-half inch hole is made in the center of the boring rod, which is used to secure the cutting tool. ATap and a set screw is a tool that the novice will need in his work.

Another hole is drilled at right angles to this one for the 1/4-inch drill shank, and tap for No. 18 1/2" inch thread. A headless set screw is threaded in, a saw cut being made on the outer end in order that it may be screwed in with a screw driver. The cutting tool should be made of the highest grade, self-hardening tool steel. Its length should not exceed one-half inch, the diameter of the boring rod. The tool

Fig. 45-B

A Simple Spark Discharge from an Induction Coil.

in a hole in the cast iron, will be found advisable to start with a heavy cut. It is done so that the sand or other silica particles that may have adhered to the cast iron when taken from the mould are immediately removed. In the following coming the subject of "Taper Cutting" will be considered.

EXPERIMENTAL PHYSICS.
(Continued from page 620)

sisted of negatively charged particles, remembering that an electric current is an electric charge in motion, and that an electric current tends to move in an electric field in a direction given by the three-finger motor rule (see Lesson 16). Hence, the presence of a field tends to make the rays converge into negatively charged electrons. The fact that these rays give a negative charge to bodies on which they fall is probably just another way of expressing the theory. The deflection of the cathode rays in magnetic and electric fields furnishes us with the necessary data for computing the size and weight of the electron. The size and weight is extremely small, the speed tremendously large (about 100,000 miles per second).

Fig. 55-B. The Cathode is Concave and Spherical. The Anode Consists of a Small Plate. The Cathode Rays Are Converged, Focus on the Platinum and Are Therefore Very Concentrated. The Platinum Incandesce. Thus Showing the "Heating Effect" of the Cathode Rays.
flected or refracted as light can, but they are different in many important respects. X-rays penetrate many substances which cathode rays cannot (X-rays pass right through, cathode rays do not). X-rays cannot be deflected by electric or magnetic fields and hence cannot, like cathode rays, be stopped by electrically charged particles. The real nature of X-rays is still unknown. Lead seems to be the most difficult substance for X-rays to penetrate. When cut they are placed on top of each other and two one-eighth inch holes drilled about one and one-half inches apart and toward one end. They must of course, be in alignment, as they are for the slider rods. The center must also be free as in one of the four and one-half inch covers fifteen holes are to be drilled for the fifteen secondary taps. The respective taps of the secondary are drawn thru in order and the ends nailed to the coil with brass nails. Care must be taken to get the openings for the sliders directly under each other. The completed secondary is shown at Fig. 4, and also the sliders and their arrangement. The sliders are made from No. 8 copper wire which is stretched taut by screws at the top of the cabinet. A screw eye is inserted into the top for hanging. The coupling, as will be described presently, and the primary is screwed in place (see Fig. 4).

THE CABINET

Very little need be said about the material for the cabinet, perhaps, as the building of this depends entirely upon the ways and means of the maker. The measurements will be given. The cabinet is made like a box except that the top and back are not put into place until the apparatus is in. The front panel is one-half inch thick, twenty-six inches high and eight and one-half inches wide (3/4 inch Bakelite makes an excellent job); the sides are six inches wide.

SWITCHES, SWITCHPOINTS AND METHOD OF VARYING THE COUPLING

The switches were made at a cost of eight cents each, using also such odds and ends as are found in any laboratory. The knobs

Learn Mechanical Drawing

Thousands of Draftsmen Wanted — Salaries $35-$100 Per Week

ARE you earning more than the average man? If not, why not offer you the best service that my school offers. I have a complete course in mechanical drawing, I offer to teach you everything I know in your own home and it is at a high-paying position of draughtsmen in one of the United States government departments or one of the great publishing houses of America. I can tell you the exact condition and in a comparatively short time you can earn $150 per month or more. It pays handsomely. The reason for this is that they are always wanted and the draughtsman who can do the work is always ready to fill the position. If you are interested, let me know.

ELECTRICAL EXPERIMENTER

January, 1919

were purchased from a hardware store. These are glass drawer knobs and have a brass shell fitted into a glass place and is cemented; also a screw is fitted into the end. Five of these are needed. The switch blade is cut from a piece of springy brass or nickel. Cut two switches and taper one end and fit them into the base of the knob and taper down one end (see Fig. 5). The other end must be made to fit the knob. A hole is drilled into this end and the blade is soldered to the brass cup; bend the contact end as shown. Also cut two pieces one and one-half inches long for the secondary switches made in the same way and one to the fifth knob solder the hand of a clock.

The switch points are common upholsterer's nails with the brass tops and small washers to the under side. After the wire has been drawn thru a hole drilled in the cabinet for it, it is twisted around the nail and then thru a hole formed pushed thru and driven into the hollow of the cup of the nail. A small amount of flux and a piece of solder about one-quarter the size of a split pea is placed into the cup which is held hollow upward. A hot iron is now applied to the solder to the nail, and the solder will melt flush and make an excellent connection. The washer is now slip over the nail and the nail driven in place. The washer es not essential but makes the heads of the switch point protrude more. (Fig. 5).

The method of varying the coupling is by a cable and drum arrangement. Rack and pinion methods need accurate workmanship for them to operate correctly, so this novel home made coupling method was devised. After the clock hand has been soldered to No. 5 knob, a twenty-four inch (circumference) wooden wheel is fastened to the screw of this knob. This wheel is placed in such a position that one end is facing the bearing is made to fit the outer end of the screw, so that there will be a fairly good axle and bearings formed, one bearing being the other end of the screw. This is then the bearing that will answer for the other end. A piece of leather is fastened in such a way as to cause friction against one part of the wheel, a piece of cloth is nailed to the wheel and wound around the groove; the cord passing over a small pulley and secured to the screw-drive of the upper end of the secondary (see Fig. 4).

ASSEMBLY

Along the mid-line of the panel and four and eight inches up from the bottom, respectively, drill two holes to fit the screws of the switches. Above each of these two holes, two smaller holes are drilled so that the end of the screw of the switch will reach to the antenna and ground. Draw the flexible wires thru; solder to switch blade (Fig. 5) and put switch in place. Place a spring on the under side of the switch to keep it tight. Describe an arc with each switch and using about two-thirds of a complete circle for the arrangement of switch points, divide them equally around the area this allows for. Drill holes for the wires of the switch points, solder to switch points as already described and connect into place. Then seventeen inches from the bottom and two inches from the mid-line each way, drill holes for the switches of the secondary. Mount the switch plates in place as per diagram for connections.

Put the top on the cabinet with the bolts (eye-bolts) for slider rods and tighten the rods; finally put on back. The diagram of the assembled coil is shown in Fig. 7.

There are many advantages of the type cabinet, as it is both compact, inexpensive and neat. It does not allow dust to settle between the windings and prevents the entrance of other foreign matter. One complete turn of the coupling knob will change the coupling completely. Accurate tuning of the primary is worked out to a very fine extent and this novel arrangement of the secondary tuning will be seen to have many merits, as any portion of the coil may be used until the desired current may also be reversed. Often the coupling will not have to be changed in order to vary the secondary, as both switches may be moved and bring another portion of the coil into play.

With a galena detector stand and using a 'radiotone' crystal, this outfit cannot be beaten and other stations were brought in that never were heard before. This may have been due to the excellency of the crystal, but the coil has something to do with it, in my estimation.

SOLAR ENGINE USES SUN'S ENERGY.

(Continued from page 607)

Messrs. Shuman, Boye and Ackerman, engineers, and built a large solar energy plant at Mead on the Nile, Egypt. This plant developed 100 h.p. The total area of the sun's concentrate was 13,500 square feet. The maximum pounds of steam generated was 12 pounds per 100 square feet of sunshine, or the equivalent, or 10,3 square feet per brake horsepower. The best hour's run developed, at atmospheric pressure, 1,442 pounds of steam. Hence (allowing 22 pounds steam per brake horsepower) the maximum output for an hour was 55.5 horsepower (about ten times better than any previous results). This means 63 brake horsepower per acre of land occupied by the plant. Moreover, no marked reduction in the horsepower produced was noticeable in the early hours of the morning or in the late hours of the afternoon.

The temperature of the sun, as aforementioned, has been calculated to be about 6,000 degrees centigrade. Several authorities point out that this terrific heat there fore precludes any possibility of the sun being a molten mass in the process of combustion. It has been thought recently by many to be a great mass of matter possessing a remarkable degree of radioactivity akin to radium. Helmholz proposed that the sun could keep on producing energy at its present rate by accounting for same on the basis of a slight annual shrinkage in its size. From observations and measurements
ELECTRICAL EXPERIMENTS

BUILDING A 3-INCH SPARK STATIC MACHINE.

(Continued from page 633)

NOVEL PHOTO OF CITY AND LIGHTNING AT NIGHT.

The photo I submit is a picture of a city at night, taken from a high mountain nearby. The object of taking the picture was to "snap" the lightning.

Rob't Sullivan, Canon City, Colo.

AT LAST—A PHOTO OF "BALL LIGHTNING."

Speaking of "Odd Photos" or something for the "bang" to worry about, I think I have here, in the form of two actual photographs, either of which contain any kind of lightning one would want, i.e., chain, ribbon or ball.

These photos were taken about six months ago (Pardon the selfishness) on the same night and about five minutes apart, during a very damaging electrical disturbance in this locality.

I may be wrong in my conception of the impression on the right side of photo No. 1 (the upper one). It is a ball lightning, but would suppose it to be such. This picture is an exposure of 30 seconds. There was no artificial light of any kind in front of the lens of the camera, and the phenomenon was not perceptible to the eye—or at least was not observed.

If this be ball lightning we then know that ball lightning is of an oscillating or pulsating nature, as is evident from the path taken by the ball. Possibly this is a potential of one sign seeking its affinity or opposite potential sign, in order that it may neutralize. Following the path of the ball it comes in at the base of the ribbon discharge at the top, travels straight across, almost parallel to the wires in the background, then it comes to rest in the upper right hand corner. It now slowly follows this star path with a few stops and makes its exit into the heavens, no doubt to join its patienty waiting other half.

Photo No. 2 (lower center) is a 3 minute exposure, during which time the camera was moved once but very slightly, as you see from the double print of the chimneys in the background. In this picture will be seen innumerable paths of the light ball where it has traveled at various speeds.

L. E. Church, Barville, Okla.

THE CITY OF SPLENDID NIGHT.

(Continued from page 623)

footed torch-bearers led the way. None of them, proud souls, ever saw their doorways in full brilliancy; but the electric, that softens rude promenances while it throws a lustrous, enchanting glow over fine design and decoration. The "City Night" forever calls me to fresh delights. I go the way of a side street at the beckon of a light and, anon, find myself before the stately pile of a building. The sky is dark, the glare of the guardian pillar of radiance that stands before it. Later I come upon a green park bordered with electric jewels. Here I seat myself and watch the trees play tag with beams of electric brilliance.

Big Money for Boys!

There is a wonderful opportunity right now for boys who like electricity. Thousands of men from the electrical industry have gone into the service and others are going every day. Boys who are ambitious and will train themselves in spare time can step into good positions and play a real part in winning the war by carrying on their work. Good salaries are offered with rapid promotions.

For 27 years the International Correspondence Schools have been training boys for success in electricity and over 200 other subjects. They will help you prepare right at home for a career in the line of electrical work you like—best—or in any other work that appeals to you. Thousands of boys, through I. C. S. training, have stepped into fine jobs, but never were opportunities so great as now.

Let the I. C. S. help you. Choose the work you like best in the coupon below, then mark and mail it today. This doesn't obligate you in the least, and it will bring you information that may start you on a successful career. This is your chance. Don't let it slip by. Make and mail this coupon today.

INTERNSATIONAL CORRESPONDENCE SCHOOLS

BOX 6172, SCRANTON, PA.

ELECTRICAL EXPERIMENTER

You may know the white lights of the night, so do I, but I also know where are to be found those more precious sights of the night, made possible by light and electricity. And so I wander lovingly through the "City of Splendid Night," and visit its shimmering shrines.

The Park at Night

WHEN next you walk abroad at night, choose Central Park, and preferably that part of it which ranges south of Seventeenth Street. Enter to the left of General Sherman Monument. Follow the friendly bypath that skirts the Japanese Lake, where the swan boats ride at anchor. I call it the "Japanese Lake" because it is the first of its kind in the park, certain trees bent and burred with weird charm, suggests a Japanese print, while the towering Plaza becomes Fuyumaya. The while you stand the lake gathers lustre from many sources, taking toll of light until its tiny, radiant body seems a great, luminous drop, drop from the eye of God.

You can't know Central Park until you see it at night, and then it is no more the park than the city surrounding it that is no more the city than its own particular charms; but it is best to consult your almanac prior to making the excursion, for no more has charged at such a time. The lights of Manhattan should not be disturbed, or marred, and a cloudy night, tho' with rain yet a long way off, is to be especially desired.

In truth some of the rarest charms of this great enclosure are the vantage points it offers for viewing the glowing city. From each hill and hollow and rustic bridge you see sights that make you whistle. New York has prepared a wonderful gallery in which you may stand and see the thousand pictures painted by the city. And the wonder of the lighting. Never have pictures been hung for exhibition with more rare understanding of the art of presentation. Never has favored critic at private view found color and arrangement, composition and subject, more effectively displayed than those he who will be guest of Central Park. The parks witness to the glory of Manhattan.

Off to the South and West flare great electric signs surmounting high buildings. Wages and laborful they hang in the sky: acrobatic, detached. As wonders of fantastic shape, winking at the night and rippling through darkness. Rows of lighted windows speak a thousand messages. From the summit of a tiny hill streaking traffic is visible in its shooting rays of warming speed.

Within the sylvan solitude the voice of the city speaks softly, and its sparkling eyes are veiled with the romance of contrast, that ever comes when Nature spreads her green mantle in the midst of man's activities.

Oh, the wonder of the city from the park; and then the wonder of the park within the city. Here Robin Hood might dwell of the colorful, the soaring, the thrilling as his finest scenes in Kensington Gardens. If you would really see all the spirits of the wood, you must dwell in the city, and then stand at the Northern limits of the Mall and, half closing your eyes and rising on tiptoe, look down its length. Fill yourself with its splendor in the every court. It is precisely lighted with soft, glowing globes. Here and there stand set pieces of statuary, grotesquely gigantic, forever trying to strike the spires in strange shadows for each competing light that falls on them from either side and from across the Mall's mile-way. From this vantage point, the whole illuminated city of New York seems as to an insomniac's point of view of the world, all the world, and that part which is the heart of the city.

As sure as you believe infancies, they are here. Some lurking behind these statues, snuggled in the robust curves of back and base. All waiting in thrilling expectancy their turns to dance and frolic in the silvery glow. The scene will surely ensnare you. Your five senses are eternally acute, you feel the pulse of Beauty, and the heart within you takes flight.

It lives the radiant poetry of Central Park. It is there for all of you who will go with vision for its picturing. It is the great gallery exhibiting the Light of Manhattan.

New York in the Rain

BLOOT out the stars. Draw a leaden mantle of cloud across the heavens. Let the skies open every pore, until earth and skies the sunlit surface of the fields are sodden, woods sullen, villages sordid, and all the open country a sticky mass of morbid moisture. But oh! Holland Amsterdam is glorious!

So fare you forth and witness the wonders of this city of cities in the rain. The perfect time is during the first silent hours of the morning. Then you may surprise it in the still splendor of its morning. The buildings stand stark, dripping, and in great masses rise triumphant thru the drenching.

The gullers are long panels of flowing mist, through which you can read in the million fractions in reflections, where treacherous corner grills suck them into roiling depths. About each light that punishes the air, you can read in the mist, there is a lazy glow. Here sparkles the jewel thrown overboard by the clouds in an effort to lighten their ballast.

As the hoisting themselves on the liquid ladder of the storm, the ascending mingled lights of the city burnish the grey vault above with golden copper, as the heartlanders picture scenes in the kettle swinging from the crane.

The romance of Masonry and Electricity is before you. It is a drama done in pour rain; in the air. The scenery is made of steel and stone, with all the city on the stage. Footlights and spotlights get their light from giant dynamos and turbines with my feet graver light than Nero made when sacrificing Rome.

Now pause, while the clouds are discharging their cargoes; if you will halt between tall houses in the rain for a full upward glance you will know somewhat of the feeling of the mountain traveller when he stands in the spray of some vast waterfall. Deep down in the calom he pauses while the rays of an unseen sun paint a rainbow on the struggling torrent at the spot where the unleashed waters hurl themselves from the cold embrace of the rocky heights.

Again you stand before great arches opening into the halls of commerce and mark the spirit mentioned. The city stands out of the night and rain and sending many-colored reflections into the shadowed recesses as fire-bearers to us in the darkness of some echoing cave.

So we see the many-sided city at its bath. The city that has been the sweetheart of an endless procession of goodly men. The city of which O. Henry sang so sweetly and of which he wrote so understandably. Great is Diana of the Madison Square Campground. Great is the Lady of Liberty Lite. But greater still is the city over which they reign.

When storm breaks at night Manhattan blossoms like a hothouse season in the downpour, and bathes majestically. And so, when drenching clouds cut off our view of the campfires of the guardsmen of the heavens, we feel an increased thrill in the shining of our faithful keepers of the curb, the stars of the street.
MAGAZINES GOING UP!

Further Increases Coming!

NOW IS YOUR CHANCE!

With this issue, the price of the EXPERIMENTER, as announced on another page, goes to $2.00 a year. With the paper market in chaos and soaring prices, printers demanding another large wage increase, engravings going up 50%, we feel sure that before spring ALL magazines will go much higher than now.

By subscribing now for from one to five years, YOU POSITIVELY WILL SAVE BIG MONEY.

The prices below are unquestionably the lowest for standard magazines that it is possible to obtain anywhere. Only by a special arrangement with the publishers are these prices possible and they are good only until December 15th, after which date all prices as given on this page are withdrawn. Make up your list at once--do not delay. If you are already a subscriber and your subscription to the EXPERIMENTER runs for a long time, you may subscribe for any other magazines by deducting the price of the EXPERIMENTER from the clubs at the rate of $1.85 (this special price allowed in clubbing with other magazines). Thus you can make up any club yourself of as many magazines as you wish from the list below.

All prices quoted are for subscribers in U. S. only. Canadian and foreign subscriptions require additional postage.

Help Wanted

Men Wanted to make Toy Soldiers, Army, Navy and other toys. Home workers on a small scale, manufacturers on a large scale. Greatest chance for industrious people for independent business. Enormous demand and future in "American-made toys." This new American market stands entirely ready. Factories have been established, people trained, machinery made with energy and success. Dealers don’t want to handle any others except “American-made.” We buy all toys now paying fair price. Experience or tools not necessary. Hundred per cent profit. Can be done on one square foot. Booklet and information free. Toy Soldier Manufacturing Co., 32 Union Square, New York.

To Ascertain the Vocation for which you are best fitted, and gain valuable information about the scope, send date of your birth and 2c. Prof. Zangl, 105 West 6th St., New York.

Monthly income paid to those who send lists of names for us at home, spare time; no supplies to purchase, no investment, expense or work required; postal bills particular. National Exchange, Box 300, New York.

Phonographs—Continued

Build Your Phonograph—"Perfection" high-quality spring and electric Motors. Reproducers, Wonderful results. Big saving since every batch is mailed for ten cents, Indiana Phonograph Supply Co., Indianapolis, Indiana.

Charlotte, N. C., Oct. 4, 1918.

Dear Sirs:

It certainly was some RESULTS. I’ve almost worn out a good typewriter just about exhaust myself writing. Well, I will have to answer it. And about “Gone Busted” buying postage stamps.

Now, I’m a-going quit, and will never do it again, and I will write to the Patent Office to answer all the letters I received from an Ad that I placed.

The letters are still coming in.—The apparatus advertised has long since been sold. Every inch of this letter is from all over the United States, AND CHINA. AND JAPAN, AND SHANGHAI, China. Can you beat that. I’m completely satisfied with it.

It’s a great life, if you don’t weaken. I THANK THE E.—Some circulation.

Very Respectfully,

402 N. Brevard St., Charlotte, N. C.

Miscellaneous

Tobacco or Snuff Habit Cured or no pay. hon. No cash ever sent on trial. Superb Co., S.A., Baltimore, Md.

Use Coupon Below. Return mail will bring you Motor.

G. D. WOOD ELECTRIC CO., Dept. 60, 441 Broadway, New York City.

HRS: Send me a MONO COIL Motor. Enclosed find 50 cents.

Address

CORE WIRE

We have been fortunate in securing thru auction several tons of guaranteed pure, double annealed Norway Iron Core Wire and are selling this wire to "Experimenter" readers

AT PRE-WAR PRICES 20cts LB.

This wire is just the thing for spark coils, transformers, etc., and in low, very much more suitable product than the usual iron wire. We absolutely guarantee the quality. Set of this kind and most所需 applicaton is now the chance to get the right material for it. As far as we know this is the only lot of Iron Norway Core Wire in the hands of any dealer at the present time, and none can be gotten until after the war. We have only two sizes left:

26 INCHES Thickness about No. 21 B and S 36 INCHES

If either of these sizes should be too long we advise cutting the wire down yourself by means of shears. It will pay you to do so as real Norway Iron Wire, sold by a few dealers last year, brought from 45c to 50c a pound. American core wire now sells for from 35c upwards per pound.

As long as the supply lasts we offer this wire as described above to our customers at the very low price of 20c a pound. Order at once.

ELECTRO IMPORTING CO., 231 Fulton St., N. Y. C.
$5. EXPERIMENTERS!

A Sample of What You Can Do With This Outfit

No. EX2002

The Boy's Electric Toys

ELECTRO IMPORTING CO.,
231 Fulton St., New York

January, 1919 ELECTRICAL EXPERIMENTER 679

THE BOY'S ELECTRIC TOYS contains enough material to make and complete over twenty-five different electrical apparatus without any other tools, except a screw-driver furnished with the outfit. The box contains the following complete instruments and apparatus which are already assembled:

Student's chronograph battery, compass galvanometer, solenoid, telephone receiver, electric lamp. Enough various parts, wire, etc., are furnished to make the following apparatus:

Electromagnet, electric candle, magnetic picture, dancing spiral, electric hammer, galvanometer, voltmeter, book for telephone receiver, condenser, sensitive microphone, short distance wireless telephone, test storage battery, shocking coil, complete telephone set, electric riveting machine, electric buzzer, dancing fishes, singing telephone, mysterious dancing man, electric jumping jack, magnetic geometric figures, rhombo, erratic pendulum, electric battery, thermo electric motor, visual telegraph, etc., etc.

This does not by any means exhaust the list, but a great many more apparatus can be built actually and effectually.

With the instruction book which we furnish, one hundred experiments that can be made with this outfit are listed, nearly all of these being illustrated with superb illustrations. So no materials, goods or supplies are necessary to perform any of the one hundred experiments or to make any of the 25 apparatus. Everything can be constructed and accomplished by means of this outfit, tools, hands, and a screw-driver.

The outfit contains 114 separate pieces of material and 24 pieces of finished articles ready to use at once.

Among the finished material the following parts are included: Chronic salts for battery, lamp socket, bottle of mercury, core wire (two different lengths), a bottle of iron filings, three spools of wire, carbons, a quantity of machine screws, flexible cord, two wood bases, glass plate, paraffin paper, binding posts, screw-driver, etc., etc. The instruction book is so clear that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the hammy with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The size over all of the outfit is 4 x 9 3/4. Shipping weight, 8 lbs. $5.00

No. EX2002. "The Boy's Electric Toys" outfit as described... $5.00

IMMEDIATE SHIPMENTS

The "Electro" Radiophone

HIGH FREQUENCY SILENT TEST BUZZER

This instrument gives a wonderful high pitched MUSICAL NOTE to the ear, impossible to obtain with the ordinary test buzzer. The ELECTRO gives a different and more musical note to the ear, and is the only instrument that can be used with the Boy's Electric Toys. "Electro" Pennison, Electric Telegraph, Current Generator, Electric Dancing Mirror, Galvanometer, etc. Space does not allow us to show the hundreds of experiments that can be performed with this wonderful outfit.

The "Electro" Telegraph

Not a toy, but a practical, home-built telegraph outfit, which not only sounds but makes the most commercial signal by producing a tone for 30 days if you can keep it going. Each operator is in the department now. Outfit consists of TWO complete telegraph instruments each measuring 5 3/4 x 2 1/2. All metal parts are highly nickel plated, including key lever. Note hard rubber knob. Telegraph Code Chart, instructions for all purposes enclosed with set, but no batteries. Outfit works on dry cells (one cell for each instrument). The "Electro" is the ONLY outfit that works both at home and on the road. Nothing to get out of order. Guaranteed to please with or money back. Price Complete as illustrated (TWO INSTRUMENTS)...

$9.00

IMMEDIATE SHIPMENTS

The "Electro" Codophone (Patent Pending)

$1.50

What this r e m a n k a b l e instrument is and does. The Electro, Codophone is positively the only instrument made that will include a 500 or 1,000 code without incident, and is based in a Wireless receiver. The compact receiving receiver equipped with a horn, talks so loud that you can hear the words all over the room, even if there is a lot of other noise. That's Not All. By plugging in the receiver cap, a tone from the lowest, softest quality, up to the loudest and bulkiest screaming sound, can be heard in a radius of 250 feet.

FOR INTERCOMMUNICATION. Using two dry cells for each instrument, the Codophone is a wonderful instrument for communicating with one wire and plenty of sound, the same as your telephone instrument. One outfit replaces both the old-fashioned learner's telegraph set, connecting key and sound, and the old-fashioned learner's telegraph set, connecting key and sound.

The Codophone is a handy, well made instrument, fool proof and built for hard work. Contacts are of hard silver to last a lifetime. Nothing to go out of order. Guaranteed to please with or money back.\n
Shipping weight, 2 lbs.

---

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your every day work is in HAWKINS ELECTRICAL GUIDES.

These books place electricity at your finger tips. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain every day language—no wasted words—every word you use—check full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask a question that Hawkins guides can't answer.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handily bound in durable black covers. You can carry each volume with you until you have mastered its contents. The 900 pages of actual information and 1,500 illustrations that make up each guide can't put them into actual use—nor will again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—ask them all the questions you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship the entire set of 10 volumes absolutely FREE.

A sign of our confidence in the guides. Pure gold does not object to being tested. Keep them a year or two and if you do not decide that you can't get along without them, return them to us and owe us nothing.

When you decide to keep them you only have to pay $1.60 down and sent the balance of $0.60 on the same payment of $1.60 a month till paid for. Use this coupon to get the books. It will pay you many times over.

THEO. AUDEL & CO.
72 Fifth Ave. New York, N. Y.
M OST of your time is mortgaged to work, meals and sleep. But the hours after supper are yours, and your whole future depends on how you spend them. Your can flitter them away on profitless pleasure, or you can make those hours bring you position, money, power, real success in life. Thousands of splendid, good-paying positions are waiting in every field of work for men trained to fill them. There is a big job waiting for you—in your present work or any line you choose. Get ready for it. You can do it without losing a minute from work or a wink of sleep, without hurrying a single meal, and with plenty of time left for recreation. You can do it in one hour after supper each night, right at home, through the International Correspondence Schools.

Yes—You Can Win Success in an Hour a Day

Hundreds of thousands have proved it. The designer of the Packard "Twin Six," and hundreds of other Engineers, climbed to success through I.C.S. help. The builders of the great Equitable Building, and hundreds of Architects and Contractors, won their way to the top through I.C.S. spare-time study. Many of this country's foremost Advertising and Sales Managers prepared for their present positions in spare hours under I.C.S. instruction.

For 26 years men in offices, stores, shops, factories, mines, railroads—in every line of technical and commercial work—have been winning promotion and increased salaries through the I.C.S. Over 100,000 men are getting ready right now in the I.C.S. way for the bigger jobs ahead.

Your Chance Is Here!

No matter where you live, the I.C.S. will come to you. No matter what your handicaps, or how small your means, we have a plan to meet your circumstances. No matter how limited your previous education, the simply written, wonderfully illustrated I.C.S. textbooks make it easy to learn. No matter what career you may choose, some one of the 280 I.C.S. Courses will surely suit your needs.

Make Your Start Now!

When everything has been made easy for you—when one hour a day spent with the I.C.S. in the quiet of your own home will bring you a bigger income, more comforts, more pleasures, all that success means, can you afford to let another single priceless hour of spare time go to waste? Make your start right now! This is all we ask. Without cost, without obligating yourself in any way, put it up to us to prove how we can help you.

Just Mark and Mail This Coupon!
THE TESLA
WIRELESS LIGHT
SEE PAGE 692
This is the Electrical Age, and this wonderful new profession is calling you. The demand for expert Electricians is greater every year and the salaries higher. Electricity is truly the greatest motive power in the world, to-day, and now is the time to enter this profession.

**YOU CAN DO THIS**

AFTER HOME STUDY

$36.00 TO $100.00 A WEEK

You can earn $36 to $100 a week and more as an Expert Electrician. If you have a common school education I can train you in a few months at home. Big lighting and power companies, municipalities, and manufacturers are always seeking trained men to handle their Electrical problems.

SPECIAL OFFER: Owing to the big demand for trained Electricians in the Government Service I am making a wonderful offer for those who enroll during October.

I Guarantee Satisfaction

Every student receives our Sealed Guarantee Bond, which guarantees to return every penny of his money if he is not entirely satisfied. No other school has made this wonderful offer, but I know the success I have brought to hundreds of my students, and I know what I can do for any ambitious young man who will give me a little of his spare time each day.

A letter that means something to every man in America who is interested in electricity

McGraw-Hill Book Co., Inc.
239 West 39th Street, New York, N. Y.

Gentlemen: In an attempt to express myself about CROFT'S NEW LIBRARY OF PRACTICAL ELECTRICITY, I have never seen and do not believe there was ever printed in the English language, a more comprehensive set of books. It is a library that is just as valuable to the novice as to the expert, because it is all practice.

Respectfully,

GUY H. PEIFER,
Chief, Doplan Silk Corporation, Hazleton, Pa.

ELECTRICITY

As Experts Know It

When we observe the ever-increasing applications and usages of electricity, we wonder if all the present openings and the newly created positions in the electrical world can ever be filled.

The ending of the war lends a new and mighty impetus to the electrical end of American industries. Salaries are soaring. There is practically no limit to the earning power of the man who educates himself in the finer points of electrical work.

Actual working facts

With the advent of the new Library of Practical Electricity, by Terrell Croft, a new era is marked in the production of self-educational electrical literature. This library satisfies a demand never heretofore met—the demand for a home study course which would bring out in detail the actual working facts. This great undertaking has been accomplished. It is a seven-year task completed.

No previous electrical training necessary

Three thousand pages, with twenty-one hundred of the latest illustrations ever put into book form. Each of the eight volumes is indexed so that everything you want to know about electricity is at the finger's end. And when you find what you want, there is not merely a short question and a short answer. You are told everything you want to know. The explanation is clear to you, regardless of whether you have had a previous knowledge of electricity or not.

Know electricity as the highest paid engineers know it

When you are studying the Croft Library of Practical Electricity, you are studying electricity as experts know it. You are acquainting yourself with the methods employed by the highest paid electrical workers and engineers in America.

This Library of eight volumes sent to you FREE for 10 days' trial

So positive are we that you will be pleased with the Croft Library of Practical Electricity that we offer to send the entire ten volumes for ten days' free use. All you need do in order to have the books sent, charges prepaid, is to fill out the attached coupon and return to us. Keep the books ten full days. Then if you are not satisfied, return them at our expense. On the other hand, if you find that they will help you, as they are helping thousands of others, send us the small sum of $2 per month for eight months.

ACT NOW

GUARDIAN

Please send me the Library of Practical Electricity showing charges printed. If satisfactory I will send $2 per month until $16 has been paid. If not satisfied I will write you for return shipping instructions.

Master Electricity By Actual Practice

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

The Oldest and Only Institution of the Kind in America

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

Over 5,000 Graduates are Successful Men in the Electrical World

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions.

Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

New York Electrical School
29 West 17th Street, New York
Tidal Power Problem Solved at Last

Tidal power is one of those long dreamed of possibilities in engineering which has occupied the minds of great philosophers for generations. Why not—for who can stand down by the ocean shore, or even by any large river having an appreciable tidal rise and fall, and fail to be impressed with the gigantic natural power here spread out before us, and let go to waste for all these years. Think of it—tens of thousands, yes, millions, of horse-power dissipating itself on our coastal and river shores every day in the year. To realize this fact fully we need but reflect for a moment. If the tide brings us a rise of several acres (many thousand cubic feet) of water, why let it fall again uselessly? Allow the water to flow, without friction, into huge basins at high tide; trap it, and when the tide falls, permit the imprisoned water to escape, but thru turbines, back to the tidal level.

That is the idea several engineers have had, but an English engineer seems to have solved the problem successfully with his specially designed tidal turbines and triple basins. His name is J. O. Boving, and his scheme is so practical that it has been proposed for the development of electric power from the tide water at the mouth of the River Dee. Mr. Boving's description of the tidal power plant is as follows:

Altho the (English) Government a few months ago took a very wise and necessary step in appointing a committee to inquire into the possibilities of water power development in the British Isles, there is one aspect of the question which does not seem to have attracted adequate attention, and that is the utilization of tidal power. The rise and fall of the tides around the English coasts vary greatly, from a maximum of nearly fifty feet in some places on the west coast to only a few feet at others. Generally speaking, the differences on the east coast are small, but on the west coast there are many river estuaries and other inlets which offer abundant possibilities for obtaining power from the tides.

Some years ago I had an opportunity of examining the possibilities of developing a tidal water power on the estuary of the River Dee, where the tidal differences are roughly thirty-five feet at highest Spring tide and thirteen feet at lowest neap tide.

The proposed River Dee Tidal Power Development As Designed By a Famous English Engineer—J. O. Boving. This View Shows His Two Basin Proposal Where the Area of the Impounded Water Would Amount To Forty-Four Square Miles. The Maximum Tidal Difference Is In This Case About Thirty-Five Feet. A Large Railway Embankment Is a Part of the Scheme. This Railway to Connect Up the Welsh Railway System With Birkenhead and Liverpool.
such a way that a power station could be worked continuously under constant head and with constant output. The plan was roughly as follows:

Supposing that we start with high tide, the flap gates leading from the sea to the high basin would be open, and the water would flow in and pass through turbines into the lower basin, the automatic flap gates to this basin being closed by the water pressure outside. This flow would continue until the level in the sea equaled that in the high basin, when the flap valves to this would slowly close. In the meantime the electric transmission is easy. In such cases the surplus power might be used during the periods when it is available for pumping up water to such reservoirs, while during the intervals, when power is required, it could be obtained thru high-pressure turbines driven by the stored-up water supplied.

It will perhaps be argued that this is a very elaborate and costly arrangement which would not pay. The problem in fact resolves itself to this: Assuming (1) that an ordinary water power in a river was developed and used for commercial purposes during twelve hours out of the twenty-four and that it was a good commercial scheme under these conditions; and (2) that a high-pressure power development could be obtained by using stored water for twelve hours of the twenty-four, and that this was also a commercially good undertaking in itself; then it must be equally sound commercially to link the two together and produce power around the twenty-four hours. In the tidal scheme the only things added to the arrangement described above are pumps, which are a negligible factor in the general costs (they would correspond to something like $3.50 per h. p.). The pipes thru which the water is pumped up are, of course, the same as those which return it to the storage reservoir plant. Everything else is in common.

The calculation for such a scheme is simple, and in the case referred to, assuming that any case as that across the Dee mouth, for railway purposes, there is no doubt that this power development would pay well. In cases where two tidal rivers flow together, the necessary conditions could be realized by connecting them. There would be nothing new in this, as the turbines would be of standard design, the variation in the head would be only such as would be allowable for in ordinary turbine plants, and the flow could be used in any periods when the power developed fell much below the average power.

However, in most cases it would be impossible to develop the three-basin idea, and it would be necessary to rely only on one inner reservoir and the sea. Obviously under such conditions the scheme would contend with very great variations in head and power. The great variations that occur in the tidal ranges at various times compel him to calculate his average head derived from neap tides.

The general idea of a one-reservoir tidal scheme is as follows: At the beginning of high tide the sluice gates are opened, and the water rushes into the inner reservoir, filling it up as quickly as possible. Then the gates are shut for a certain time, until the water level outside has fallen by an equal or greater difference in level between the reservoir and the sea. (See detailed illustration of one reservoir scheme.) The sluice gates are now opened and kept in operation under virtually constant head, while the level in the reservoir falls at the same time as the tide. Some time before the lowest level of the tide the turbines are shut off, the gates opened, and the remaining water in the reservoir allowed to rush out with the lowest tide. Then the gates are closed, the tide rises outside until the difference in level between the sea and the reservoir has again reached the agreed level, the turbines are started, and the same procedure is gone thru for the rising tide as just described for the falling. Thus for certain definite periods power is obtained at a straight constant rate, but in the intervals no power is produced.

Up until now we have been satisfied to mine and burn coal, prospect for oil gushers, and, in fact, have tried out about every expensive source of power we could think of. This comes of prosperity. America is rich, and the keynote of the future is "expensive." Design, develop, build,—do all these things—say our great philosophers and educators, but do them FAST. Speed is a fine thing—in its place; but there is bound to be a big bill to pay, some day. Why not live and work efficiently; not necessarily in a slow, plodding, unenlightened way, but in an economical manner. Coal and oil will not last forever. If you have ever visited Holland, you have doubtlessly been impressed with the simplicity of things and those windmills. There is a fine bit of antique engineering. The Hollander is using the force of nature—the wind. Besides these you will find in all parts of Europe the ever-present water wheel and turbine. Examine the steady progress of water power in most cases; but do the American farmers and developers put the free wind and water power to work? Not, they do NOT. They would rather spend a thousand dollars or so for a gasoline engine and then work their heads off for the rest of their lives to get the same. If you can see hundreds of windmills and waterwheels rusting to pieces all over the country. A great pity and a prodigious waste.

Sweden, which is rich in water power, sends electricity across the sound to Denmark.
Producing Rain by Electricity and X-Rays

FROM time to time in the world's history, there have been schemes promulgated for and attempts made at producing rain by artificial means under the control of man. One of the most promising of the recent schemes for producing rain-fall at any desired time, providing there happened to be aqueous particles contained in the atmosphere, is that due to an Australian scientist, John Graeme Balsillie. He has taken out patents on his system of producing rain-fall electrically, and one of his latest American patents is here pictured and described.

The illustration shows how Mr. Balsillie proposes to send up a series of balloons or large box kites of sufficient size to carry an extra large X-ray tube, and also capable of supporting two thin electric wires of considerable length. As the inventor states in his patent, his invention "consists in electrical means for assisting and promoting under suitable meteorological conditions the formation of aqueous particles in the atmosphere and assisting in promoting the deposition of water particles (rain-fall) from the atmosphere, and further to provide suitable apparatus for producing the necessary electrical conditions for that purpose." This balloon may be controlled from a tractor truck which can speed over the country to various points wherever it may be desired, and a portable gasoline engine and dynamo outfit on the truck may supply the necessary current for operating the powerful X-ray tube carried by the balloon, as shown in the illustration, and also for developing the high potential current, about 350,000 volts, which is employed for charging the metallicized surface of the balloon.

As has been pointed out in previous articles on similar inventions in this Journal—and as substantiated by the opinion of several well-known scientists, included Dr. Henryt Arocken, the Aroctic explorer, of New York—the inventor informs us in his patent that his discovery is susceptible to practical use only when the cooling of aqueous vapor resulting from its expansion in elevated regions of the atmosphere and other natural influences brings the vapor above the saturation point, so that condensation becomes possible.

It has been ascertained that ions, produced in this case by Mr. Balsillie by the powerful X-rays, which ionize the atmosphere in the vicinity of the balloon, may act as nuclei, upon which, under certain conditions, water vapor will condense. Aqueous particles comprising cloud, fog or mist are invariably electrified by natural causes, and also their electrification is of one sign, the potential or voltage distribution through the mass is uneven. Aqueous particles of approximately equal dimensions and potential will therefore naturally repel each other, and no condensation will result. However, nuclei, upon which water condensation may take place, can be created by ionizing the atmosphere, such as by powerful X-rays, and further if under normal conditions, a mutual repulsivity of charge of the aqueous particles is altered to a condition of mutual attraction, then the presence of such aqueous particles will be assisted, and rain caused to fall.

As the accompanying detail illustration shows, if a metal plate (or the metallicized surface of the balloon) is charged at a very high potential of say several hundred thousand volts, then the electrified body serves to give an opposite charge to the aqueous particles floating in the atmosphere.

The aqueous particles thus become positive of a charge of opposite sign to that which they originally had. This charge of opposite sign, however, is not and cannot be communicated instantaneously to all the particles in said zone. The particles in close proximity to the source of electrification are rapidly charged by electrostatic induction with a charge of opposite sign to the one they have acquired. The particles in close proximity to each other, are posset of electrical charges of opposite sign. Such particles consequently attract each other, coalesce, and then fall as rain, under the influence of gravity.

The apparatus used for producing the high potential uni-directional current for charging the metallicized balloon surface is produced by a transformer and interrupter supplied from a dynamo or other source on the ground. The secondary circuit of the induction coil is equipped with rectifying valves in order to rectify the current. Similar apparatus, also provided with vacuum.

Moving Platform for New York's Cross-Town Subway

By H. WINFIELD SECOR

SUBWAY commuters and others who use New York's great underground transportation systems can be promised a less crowded and harrier in the past several months by the various difficulties occasioned by the change in the two principal north and south lines of the system. In other words, the subway system was changed over a few months ago from the old familiar "Z" system to the new so-called "H" system, which gives a continuous east-side and west-side subway express route, the—the of the "H" connecting at the present time by shuttle trains running under 42nd Street between the Grand Central Station and the Times Square Station. The Grand Central Station is located at 42nd Avenue and 42nd Street, while the Times Square Station is located on the west side at the junction of 7th Avenue, Broadway, and 42nd Street.

For several reasons the shuttle train service seems apparently not to be the best solution of the problem confronting the company. The traffic is rapidly and quickly transferring the cross current of traffic between these two stations, and therefore Public Service Commission No. 1 has ordered a continuous moving platform such as here illustrated to be installed in the space now occupied by two of the four tracks. Mr. Smith, the general staff engineer, has decided that the original idea called for the installation of this continuous moving platform on the two northerly tracks of the subway system, leaving the two southerly tracks for shuttle service, which might be necessitated when the moving platform might get into an order, where the shuttle train service could be put in use. Also, the two tracks could be used for the extension of the Queensboro Subway system, which is another proposal in the minds of the New York City Rapid Transit engineers, so that eventually the Queensboro trains which now end their westward run at the Grand Central Station, two levels under the ground as here illustrated, will terminate at Times Square.

In a recent interview with Mr. M. Everhart, the chief engineer of the construction concern which will build this gigantic moving platform, six thousand feet in length and capable of carrying a crowd of people at one time, a different suggestion was made concerning the location of this proposed continuous moving platform. Instead of having tracks over the space on which the two northerly tracks will run, Mr. Smith pointed out that it is much more feasible and practical in every way to have it occupy the present position of the extreme northerly and southerly tracks, leaving two tracks in the center for emergency shuttle train service or for the extension of the Queensboro system to Times Square. This consideration of the design and layout of the moving platform system is even more important, it is thought, for the reason that if the return loop of the platform pass along in the position now occupied by one of the inside tracks of the original design, this track might be at right angles to any point desired, excepting at the terminal stations at either Grand Central or Times Square.

As a consequence there should be not less than three moving platforms in any case, each moving at a different speed, the outer one at three miles, the intermediate at six miles, and the inner platform carrying the seats, at nine miles per hour. Therefore, as Mr. Smith suggested, in discussing Mr. Whitney's original idea, it would be necessary for passengers traveling east to attempt to cross a high speed (9-mile per hour) platform moving west. To give the greatest service, and to obviate the possibility of injury for both passengers on the moving platform at any point along the entire route, the moving platform system should occupy the space now used by the two center or the two outside tracks. In other words the two moving platforms would have to have adjacent to them a stationary platform, provided with suitable exits and entrances. If the present shuttle train service should be extended to connect with other subways as well as between 7th Avenue to Times Square, the trains, Mr. Smith explained, would not conflict with the moving platforms, because the latter would be operated only on the train stations. In this case the moving platform would be used merely for the collection and distribution of passengers within the area of the Times Square system, and of its best of it.

Concerning the initial cost of this great moving platform it is estimated that it would be approximately $15,000,000, and that it would take six months to install. But the present time of the engineers of the Public Service Commission and the subway design is very efficient, and the cost of the moving platform, concern, are busy trying to find a satisfactory space for the platform return loops at the station ends. Times Square as these return loops being quite an extensive affair, the minimum diameter of the loop being about 130 feet. The moving platform idea is not so entirely new or untried, as it might appear at first. They have been built and used at different stations years ago, both abroad and in the United States. The same concern which is now designing the one for installation under 42nd Street, had one in successful operation at the World's Fair in Chicago, 4,400 feet in length. Visitors to that Fair will undoubtedly remember the great attraction, the platform which was designed to transport to the total of 150 horsepower, which had a carrying capacity of 6,000 passengers. On Chicago it is twice the daily traffic of the Brooklyn Bridge—were carried without any inconvenience. The total live and dead weight was 900 tons. As aforementioned, the new platform proposal for 42nd Street, New York City, is approximately 6,000 feet in length, with a capacity of 10,000 passengers, and will require electric motors distributed along its length to a total of about 250 horsepower.

Undoubtedly some of our readers will be interested in some of the more or less obvious technical details and just how the various parts are to operate. Thru the courtesy of Mr. M. Everhart Smith, we are pleased to have this illustration, which has been submitted to the editors. First, the three moving platforms, moving at three gradually increasing velocities, will be constructed, on board it without being thrown over or requiring acrobatics, will not be exactly on the same track, but only a very slight, even, and will overlap the next succeeding platform, this practice having been found the best from past experience. The detailed drawings in the accompanying illustration show how the platform is made in a large number of jointed sections, each of which is provided with a flexible coupling so as to easily negotiate the curves at the station loops. Under the whole moving platform there is installed a stationary series of wheels or pulleys mounted on axles. The depending rails of the various platforms rest on the respective pulleys or wheels between the platform rails in each case, as the drawing indicates. At about every eighth or tenth pulley there will be located a small electric motor connected to the drive of the particular pulley. All together about 250 horsepower in electric motors will be required, which would practically mean that the two thousand horse-power in electric motors necessary for the operation of a ten-car subway train.

The matter of seats on the third or high-speed platform is a very flexible one, and at first most probably but one row of seats will be installed, as the illustration shows, but later, more than at least two and perhaps three rows might be used by women, as Mr. Smith pointed out. Another feature at this point is that those in a hurry can walk along any one of the moving platforms. For instance, a man walks at the rate of four miles per hour on the nine mile per hour platform. He will actually be moving in that particular direction at a rate of two miles per hour. In addition to the advantages of constantly moving platforms with no waits for shuttle trains, and with entrances and exits at every cross-street, such as at Madison, Fifth and Sixth Avenues, an immense income could be derived from the storerooms and advertising spaces along the platforms.

Referring once more to the platform and its operation, it will be seen how the motor-driven wheels under the rails of the platform sections will cause these sections to be propelled forward in a direction depending upon the rotation of the wheels. The end-wise junction between the sections of the moving platforms is on an even level, and they are closely curved on the order of a knuckle-joint so that no gap occurs between the rails of the moving platforms or is also desined as to correspond both at front and back, and thus this unique design permits of the section allowing smooth and easy loop curves in a smooth manner. Light steel posts, containing straps for the use of the "strap hangers" brigade, without which life could be a large part of its vim and pep, will be provided, as the illustration shows. Of course the chaps on the way home from the club will have to remove their hat in this English say—well—WELL, by that time the Nation will be dry anyway, so we should worry!! And besides the late home-comers using the platform during the "G. M. home" will most probably be lucky enough to find it pretty well deserted in the event that they have drunk up many glasses of near-beer or cherry flip.

Regarding the heating of this long tunnel, Mr. Smith has suggested that during the cold weather of the tunnel system, in which the moving platform is installed, could be steam-heated at regular intervals, and also special ventilating fans and baffle walls could easily be provided at the various stations, as well as at the terminals, so as to ensure the proper ventilation and heating of the passageway.
February, 1919

ELECTRICAL EXPERIMENTER

689

(For full description see opposite page)
The Unknown Purple

By DOROTHY KANT

What would you do if you had the power to make yourself invisible—not by means of Aladdin’s wonderful lamp, but by an actual scientific invention? Ask Dad, he knows! Thus, for instance, it certainly would be a boon to some delicately balanced husband, homeward bound, to escape the shark eye of his better half, not to mention into a play that seems to have so big a success with New York’s critical audiences.

The scientist in this play who is incidentally our hero uses his invention to wreak vengeance upon his unfaithful wife and her paramour by making himself invisible and by playing pranks with the fortunes of both wife and lover.

But how does he do it and at the same time raise the tension of the audience to such a height that you can hear a “dew” drop?

One of our ingenious readers not so long ago wrote, jocularity, suggesting that we run a perfectly blank cover on the magazine under the caption “Camouflaged Ship on the Ocean”. The joke was supposed to be that the ship was so well camouflaged that you could not see it at all—hence the blank cover page! The authors of the “Unknown Purple” evidently used a similar line of reasoning on which they built up their play.

The problem was how to show a man walking across the stage who is supposed to be invisible. The answer is simplicity itself: don’t show him at all, but make the audience believe that he is really there. This is certainly simplicity reduced ad absurdum. But in order to show that the man was really there—alack, of course he wasn’t—something had to be done, else the audience would not be sufficiently impressed and would take the hero’s “absent treatment” as a joke. So the authors simply have a purple spot light arranged overhead, which light travels at a slow gait across the stage, and the lighting effects are so cleverly arranged that the audience obtains the impression that the invisible man is ever the purple light appeared, and when our invisible hero was on the stage, the effect was still further heightened by a certain low buzz produced by a spark coil vibrator or the like and which buzz was supposed to emanate from the substance in the hero’s hand which created the invisibility. Needless to say it had the desired effect and many a young damsel felt purple goose skin take the place of her natural one, and becoming the recipient of creeps and thrills such as never were hers before.

Of course, the usual stage tricks were resorted to, as for instance when our noble hero stealthily and invisibly opens the safe to abstract certain important papers. We thus see the purple spot or ray centered on the safe, amidst the mysterious buzzing sound—then the click of the combination as it is turned—the opening of the safe door slowly and mysteriously. Yes, you guess it, the safe was opened by invisible threads or strings, as no hands or anyone were visible. A similar trick was used whenever the hero entered the stage by means of the door. The door, of course, opened without any visible mechanical means and the solution in this case too obviously was strings or threads. There was only one scene that was staged elaborately and that was in the

(Continued on page 748)
Zeppelin Flew 4,130 Miles Round Trip from Bulgaria to Khartoum

A RECENT wireless dispatch from Berlin correspondsent contains some most interesting news concerning Teutonic developments in giant aircraft. It is said that the Germans are busy constructing a mammoth airplane intended to cross the Atlantic Ocean. This huge aerial craft, now under construction, is said to be able to travel at a speed of 188 feet per second, and it is to be engined by 3,000 horse-power in petrol motors.

The Teuton aerial flight experts are said to be busy constructing a gigantic Zeppelin craft at Friedrichshafen, which is to be propelled by nine engines and eight propellers. It will have a carrying capacity of one hundred passengers, and it is hoped that the international situation will clear up so that the first test flight of the giant might take place this coming July. The voyage across the Atlantic from a point in Germany to New York City is expected to take about forty hours.

But coming down to cold facts and past performances, the accompanying illustration shows one of the most remarkable aerial trips accomplished during the great war, in which a giant Zeppelin flew from Jamboli, in Bulgaria, to a point over Khartoum, on the river Nile in Africa, a distance as the crow flies of 2,005 miles, and a distance of 2,500 miles for the non-stop return trip. The Zeppelin carried a crew of twenty-two men besides twenty-five tons of ammunition and medicines for the Teuton army in German East Africa. The great craft glided from its hangar at Jamboli at eight o'clock on the morning of November 21st, 1917. On the night of November 22nd-23rd, the monster airship arrived over Khartoum, when it picked up a wireless message from the German raider at Khartoum ordering it to return at once, as the Government at Berlin had ascertained in the meantime that the majority of Gen. von Lettow-Worbeck's troops had surrendered to the Allies. Consequently the airship turned about in mid-air without making a landing and arrived at Jamboli at eight o'clock in the morning on November 25th. The technical director of the factory where this aerial craft was built has stated that a ship of this type was easily capable of flying from Berlin to New York and returning without a stop. The air-line distance from Berlin to New York City is approximately 3,930 miles, and the round trip distance would be 7,860 miles, or nearly eight thousand miles. Talking of dirigible gas-bag types of aircraft, the U.S. Navy Department has just announced a remarkable new gas, which is available by a new process. Discovery of this new inert, non-inflammable gas for balloons, dirigibles and other lighter-than-air owned by the Lone Star Gas Company, the statement said, and a ten-inch pipe line to cost $1,050,000 is being laid for a distance of ninety-four miles from the wells to a plant at North Fort Worth where the gas will be compressed into cylinders for shipment to the balloon fields. High proof gasoline is obtained in a ratio of about five gallons of gasoline for every 11 cubic feet of gas, it was said, and after the per cent of "argon" is removed, by agreement with the oil company, the remainder of the gas is turned into the city mains of Fort Worth and Dallas.

The Department estimates that the plant at North Fort Worth, designed by the Navy Bureau of Yards and Docks, and which will cost $900,000 will be completed by April.

INJURING THE EYES BY PHOTOGRAHY.

When one sees so many veteran photographers, both amateur and professional ranks, suffering from astigmatism, one wonders what is the actual cause of this distressing optical defect. On inquiry, it will be found that in many cases the eyes were strained during the early days of dryplate-photography, when the plates were then coated with a very slow emulsion—were handled, and examined during development, by the light of a deep ruby oil-lamp. Amateurs at first used advisedly a small pocket-lamp, and undoubtedly incurred serious injury to the sight. Later—than goodness—light of greater volume was employed, ruby light being also superseded by orange light; preferably fabric instead of glass being used to expose the dryplates sparingly to the rays of this brighter light. Now the photographer confronts the danger of ruining his eyes from exposure to the electric arc when used for printing purposes. To look at the bare arc is obviously injurious to the sight. Arc-rays reflected from the surface of the negatives are also bad for the eyes. A good plan is to use a printing-lamp in which only reflected light is directed on the negatives, or to use a printing-cabinet in which the arc is enclosed, care being taken to cover up empty spaces with strips of cardboard so that the arc or its reflections do not reach the printer's eyes.
Famous Scientific Illusions

By NIKOLA TESLA

Written specially for the Electrical Experimenter

In this original and revolutionizing discussion, Nikola Tesla gives us something really new to think about. First—Does the moon rotate on its axis? Second—Is the Franklin pointed lightning rod correct in theory and operation? Third—Do wireless signals fly thru space by means of so-called Hertzian waves in the ether, or are they propagated thru the earth at prodigious velocity by means of earth-bound oscillations? World-famous conundrums these—questions which have been answered in many ways by some of the greatest scientists. Dr. Tesla explains these three predominant scientific fallacies in a masterly way, so that everyone can understand them.

The human brain, with all its wonderful capabilities and power, is far from being a faultless apparatus. Most of its parts may be in perfect working order, but some are atrophied, undeveloped or missing altogether. Great men of all classes and professions—scientists, inventors, and hard-headed financiers—have placed themselves on record with impossible theories, inoperative devices, and unrealizable schemes. It is doubtful that there could be found a single work of any one individual free of error. There is no such thing as an infallible brain. Invariably, some cells or fibers are wanting or unresponsive, with the result of impairing judgment, sense of proportion, or some other faculty. A man of genius eminently practical, whose name is a household word, has wasted the best years of his life in a visionary undertaking. A celebrated physicist was incapable of tracing the direction of an electric current according to a childishly simple rule. The writer, who was known to recite entire volumes by heart, has never been able to retain in memory and recapture in their proper order the words designing the colors of the rainbow, and can only ascertain them after long and laborious thought, strange as it may seem.

Our organs of reception, too, are deficient and deceptive. As a semblance of life is produced by a rapid succession of inanimate pictures, so many of our perceptions are but trickery of the senses, devoid of contrary to all observation, this planet rotates around the sun; the recognition of Descartes that the human being is an automaton, governed by external influence and the idea that the earth is spherical, which led Columbus to the finding of this continent. And that the minds of individuals supplement one another and science and experience are continually eliminating fallacies and misconceptions, much of our present knowledge is still incomplete and unreliable. We have soothed in mathematics which cannot be disproved. Even in pure reasoning, free of the shortcomings of symbolic processes, we are often arrested by doubt which the strong-
est intelligences have been unable to dispel. Experimental science itself, most positive of all, is not unfailing.

In the following I shall consider three exceptionally interesting errors in the interpretation and application of physical phenomena which have for years dominated the minds of experts and men of science.

I. The Illusion of the Axial Rotation of the Moon.

It is well known since the discovery of Galileo that the moon, in travelling thru space, always turns the same face towards the earth. This is explained by stating that while passing once around its mother-planet the lunar globe performs just one revolution on its axis. The spinning motion of a heavenly body must necessarily under go modifications in the course of time, being either retarded by resistance internal or external, or accelerated owing to shrinking and other causes. An unalterable rotational velocity thru all phases of planetary evolution is manifestly impossible. What wonder, then, that at this very instant of its long existence our satellite should revolve exactly so, and not faster or slower. But many astronomers have accepted as a physical fact that such rotation takes place. It does not, but only appears so; it is an illusion, a most surprising one, too.

I will endeavor to make this clear by reference to Fig. 1, in which E represents the earth and M the moon. The movement thru space is such that the arrow, firmly attached to the latter, always occupies the position indicated with reference to the earth. If one imagines himself as looking down on the orbital plane and follows the motion he will become convinced that the moon does turn on its axis as it travels around. But in this very act the observer will have deceived himself. To make the delusion complete let him take a washer similarly marked and supporting it rotatably in the center, carry it around a stationary object, consider keeping the arrow pointing towards the latter. Tho to his bodily vision the disk will revolve on its axis, such movement does not exist. He can dispel the illusion at once by holding the washer fixedly while going around. He will now readily see that the supposed axial rotation is only apparent, the impression being produced by successive changes of position in space.

But more convincing proofs can be given that the moon does not, and cannot revolve on its axis. With this object in view attention is called to Fig. 2, in which both the satellite, M, and earth, E, are shown embedded in a solid mass, M, (indicated by stippling) and supposed to rotate so as to impart to the moon its normal translatory velocity. Evidently, if the lunar globe could rotate as commonly believed, this would be equally true of any other portion of mass M, as the sphere M, shown in dotted lines, and then the part common to both bodies would have to turn simultaneously in opposite directions. This can be experimentally illustrated in the manner suggested by using instead of one, two overlapping rotatable washers, as may be conveniently represented by circles M and M, and carrying them around a center as E, so that the plain and dotted arrows are always pointing towards the same center. No further argument is needed to demonstrate that the two gyrations cannot co-exist or even be pictured in the imagination and reconciled in a purely abstract sense.

The truth is, the so-called "axial rotation" of the moon is a phenomenon deceptive alike to the eye and mind and devoid of physical meaning. It has nothing in common with real mass revolution characterized by effects positive and unmistakable. Volumes have been written on the subject and many erroneous arguments advanced in support of the notion. Thus, it is reasoned, that if the planet did not turn on its axis it would expose the whole surface to terrestrial view; as only one-half is visible, it must revolve. The first statement is true but the logic of the second is defective, for it admits of only one alternative. The conclusion is not justified as the same appearance can also be produced in another way. The moon does rotate not on its own, but about an axis passing thru the center of the earth, the true and only one.

The unifying test of the spinning of a mass is, however, the existence of

![Image](https://via.placeholder.com/150)
energy of motion. The moon is not possess of such

we have experimental evidence. Irrespective of this so exact a coincidence between the axial and orbital periods is, in itself, immensely improbable for this is not the permanent condition towards which the system is tending. Any axial rotation of a mass left to itself, retarded by forces external or internal, must cease. Even admitting its perfect control by tides the coincidence would still be miraculous. But when we remember that most of the satellites exhibit this peculiarity, the probability becomes infinitesimal.

Three theories have been advanced for the origin of the moon. According to the oldest suggested by the great German philosopher Kant, and developed by Laplace in his monumental treatise "Mécanique Céleste", the planets have been thrown off from larger central masses by centrifugal force. Nearly forty years ago Prof. Gregor H. Darwin in a masterful essay on tidal friction furnished mathematical proofs, deemed unrefutable, that the moon had separated from the earth. Recently this established theory has been attacked by Prof. T. J. J. See in a remarkable work on the "Evolution of the Stellar Systems", in which he propounds the view that centrifugal force was altogether inadequate to bring about the separation and that all planets, including the moon, have come from the depths of space and have been captured. Still a third hypothesis of unknown origin exists which has been examined and commented upon by Prof. W. H. Pickering in "Popular Astronomy of 1907", and according to which the moon was torn from the earth when the latter was partially solidified, this accounting for the continents which might not have been formed otherwise.

Undoubtedly planets and satellites have originated in both ways and, in my opinion, it is not difficult to ascertain the character of their birth. The following conclusions can be safely drawn:

1. A heavenly body thrown off from a larger one cannot rotate on its axis. The mass, rendered fluid by the combined action of heat and pressure, upon the reduction of the latter immediately stiffens, being at the same time deformed by gravitational pull. The shape becomes permanent upon cooling and solidification and the smaller mass continues to move about the larger one as tho it were rigidly connected to it except for pendular swings or librations due to varying orbital velocity. Such motion precludes the possibility of axial rotation in the strictly physical sense. The moon has never sped around as is well demonstrated by the fact that the most precise measurements have failed to show any measurable flattening in form.

2. If a planetary body in its orbital movement turns the same side towards the central mass this is a positive proof that it has been separated from the latter and is a true satellite.

3. A planet revolving on its axis in its passage around another cannot have been thrown off from the same but must have been captured.

II. The Fallacy of Franklin's Pointed Lightning-Rod.

The display of atmospheric electricity has since ages been one of the most marvelous spectacles afforded to the sight of man. Its grandeur and power filled him with fear and superstition. For centuries he attributed lightning to agents god-like and supernatural and its purpose in the scheme of this universe remained unknown to him. Now we have learned that the waters of the ocean are raised by the sun and maintained in the atmosphere delicately suspended, that they are wafted to distant regions of the globe where electric forces assert themselves in upsetting the sensitive balance and causing precipitation, thus sustaining all organic life. There is every reason to hope that man will soon be able to control this life-giving flow of water and thereby solve many pressing problems of his existence.

Atmospheric electricity became of special scientific interest in Franklin's time. Faraday had not yet announced his epochal discoveries in magnetic induction but static fractional machines were already generally used in physical laboratories. Franklin's powerful mind at once leaped to the conclusion that fractional and atmospheric electricity were identical. To our present-day view this inference appears obvious, but in his time the mere thought of it was little short of blasphemy. He investigated the phenomena and argued that if they were of the same nature then the clouds could be drained of their charge exactly as the ball of a static machine, and in 1749 he indicated in a publish memoir how this could be done by the use of pointed metal rods. Curing Soldiers' Ills with Electricity

By PAULINE BERGINS

Electricity is playing no mean role in the vast reconstruction work now being carried on in the great Red Cross as well as Army and Navy hospitals throughout the country. Not only has the electric current been cleverly employed in many diversified ways to treat the many ills and maladies with which the soldiers and sailors have been afflicted in this country, but thousands of these appliances have been and are being used every day in the field hospitals in France, and in other lands which were not many months ago raging battlefields. Portable yet powerful X-ray ambulances sped over the battlefields but a few miles behind the front line trenches, ever ready to loan a helping hand in the merciful work of the medical corps. And not only do we find in these shell-torn regions the invaluable

nervous cases caused by excessive fatigue, and for over-strained muscles and cords. There are more shell-shock victims from the great World War than there have been in any other. And, therefore, the fact that the Bergonie electric chair will help to alleviate and cure these cases, is indeed a great blessing.

It might be said that the majority of shell-shock are cured suddenly and instantaneously. A large French hospital just

X-ray machines, but many other appliances such as electric heating devices for the treatment of "trench fever," electric sterilizers and cauterizers, Faradic outfits for the treatment of lameness and rheumatism, electric light baths, etc.

The accompanying photographs show several very interesting and practical applications of the electric current for the treatment of war ills. The photograph, Fig. 1, showing an American soldier seated in the large reclining chair, was taken at Fort MacPherson, Ga. This curious and complicated looking electric outfit comprises one of the most wonderful electro-medical devices ever invented—the "Bergonie" Electric Chair. The Bergonie invention involves the application of low voltage electric currents of peculiar wave form to the patient's body while seated in the chair shown, the body being weighted with a number of sand bags. The switch-board in the background contains a number of regulating rheostats and motor-driven interrupters as well as measuring instruments, such as a voltmeter and milliampere meter for indicating the strength of the current applied to the patient. The Bergonie chair treatment produces rhythmic pulsations in the nerves and muscles and has been found very efficacious for shell-shock victims as well as for treating severe

prior to the signing of the armistice there

(Continued on page 748)
THE progressive development of man is vitally dependent on invention. It is the most important product of his creative brain. Its ultimate purpose is the complete mastery of mind over the material world, the harnessing of the forces of nature to human needs. This is the difficult task of the inventor who is often misunderstood and unrewarded. But he finds ample compensation in the pleasing exercises of his powers and in the knowledge of being one of that exceptionally privileged class without whom the race would have long ago perished in the bitter struggle against pitiless elements.

Speaking for myself, I have already had more than my full measure of this exquisite enjoyment, so much that for many years my life was little short of continuous rapture. I am credited with being one of the hardest workers and perhaps I am, if thought is the equivalent of labor, for I have devoted to it almost all of my waking hours. But if work is interpreted to be a definite performance in a specified time according to a rigid rule, then I may be the worst of idlers. Every effort under compulsion demands a sacrifice of life-energy. I never paid such a price. On the contrary, I have thrived on my thoughts.

In attempting to give a connected and faithful account of my activities in this series of articles which will be presented with the assistance of the Editors of the ELECTRICAL EXPERIMENTER and are chiefly addrest to our young men readers, I must dwell, however reluctantly, on the impressions of my youth and the circumstances and events which have been instrumental in determining my career.

Our first endeavors are purely instinctive, promptings of an imagination vivid and asserts itself and we of the greatest moment and may shape our very destinies. Indeed, I feel now that had I understood and cultivated instead of suppressing them, I would have added substantial value to my bequest to the world. But not until I had attained manhood did I realize that I was an inventor.

This was due to a number of causes. In the first place I had a brother who was gifted to an extraordinary degree—one of those rare phenomena of mentality which biological investigation has failed to explain. His premature death left my parents disconsolate. We owned a horse which had been presented to us by a dear friend. It was a magnificent animal of Arabian breed, possesst of almost human intelligence, and was cared for and petted by the whole family, having on one occasion saved my father's life under remarkable circumstances. My father had been called one winter night to perform an urgent duty and while crossing the mountains, infested by wolves, the horse became frightened and ran away, throwing him violently to the ground. It arrived home bleeding and

Mr. Tesla at the Age of 23.

Mr. Tesla at the Age of 29.

Mr. Tesla at the Age of 39.
exhausted, but after the alarm was sounded immediately dashed off again, returning to the spot, and before the searching party were far on the way they were met by my father, who had recovered consciousness and remounted, not realizing that he had been lying in the snow for several hours. This horse was responsible for my brother’s injuries from which he died. I witnessed the tragic scene and altho fifty-six years have elapsed since, my visual impression of it has lost none of its force. The recollection of his attainments made every effort of mine seem dull in comparison.

Anything I did that was creditable merely caused my parents to feel their long-cherished keen disappointment. So I bowed down with little confidence in myself. But I was far from being considered a stupid boy, if I am to judge from an incident of which I have still a strong remembrance. One day the Aldermen were passing thru a street where I was at play with other boys. The oldest of these venerable gentlemen—a wealthy citizen—passed to give a silver piece to each of us. Coming to me he suddenly stopped and exclaimed, “Young man, look in my eyes.” I met his gaze, my hand outstretched to receive the much valued coin, when, to my dismay, he said, “No, not much, you can get nothing from me, you are too smart.” They used to tell a funny story about me. I had two old aunts with wrinkled faces, one of them having two teeth protruding like the tusks of an elephant which she buried in my cheek every time she kissed me. Nothing was so bad as the prospect of being hugged by these as affectionate as unattractive relatives. It happened that while being carried in my mother’s arms they asked me who was the prettier of the two. After examining their faces intently, I answered thoughtfully, pointing to one of them, “This here is not as ugly as the other.”

Then again, I was intended from my very birth for the clerical vocation and this thought continue to oppress me. I longed to be an engineer but my father was inflexible. He was the son of an officer who served in the army of the Great Napoleon and, in common with his brother, professor of mathematics in a prominent institution, had received a military education but, singularly enough, later embraced the clergy in which vocation he achieved eminence. He was a very erudite man, a veritable natural philosopher, poet, and writer and his sermons were said to be as eloquent as those of Abraham a Sancta-Clara. He had a prodigious memory and frequently recited at length from works in several languages. He often remarked playfully that if some of the classics were lost he could restore them. His style of writing was much admired. He penned sentences short and terse and was full of wit and satire. The humor which he made use of was always peculiar and characteristic. Just to illustrate, I may mention one or two instances. Among the help there was a cross-eyed man called Mane, employed to do work around the farm. He was chopping wood one day. As he swung the ax my father, who stood nearby and felt very uncomfortable, cautioned him, “For God’s sake, Mane, do not strike at what you are looking at but what you intend to hit.” On another occasion he was taking out for a drive a friend who carelessly permitted his costly fur coat to rub on the carriage wheel. My father reminded of it saying, “Pull in your coat, you are ruining my tire.” He had the odd habit of talking to himself and would often carry on an

**NIKOLA TESLA**

**THE MAN**

*By H. Gernaback*

The door opens and out steps a tall figure—over six feet high—gaunt but erect. You are appalled. You are become conscious at once that you are face to face with a personality of a high order. Nikola’s hands shake your hand with a powerful grip, surmounting for a moment your surprise. A winning smile from piercing light blue-gray eyes, set in extraordinarily deep sockets, fascinates you and makes you feel at once at home. You are left for some time immeasurable in its ordinariness. Not a speck of dust is to be seen on his table, desk, everywhere. Everything is in its place. And if the man himself, immeasurable in attitude, orderly and precise in his every move, were a dark trolley coat, he is entirely devoid of all jewelry. No ring, no watch-chain can be seen.

Tesla—speaks—a very high almost falsetto voice. He speaks quickly and very convincingly. It is the man’s voice chiefly which fascinates you.

As he speaks you find it difficult to take your eyes off his own. Only when he speaks to others do you have a chance to study his eyes. They have a high forehead with a bulge between the eyes—the never-ending sign of exceptional intelligence. Then the long, well-shaped nose, proclaiming speciality.

How does this man, who has accomplished so much in a very young age and managed to surprise the world with more and more new inventions as he grows older? How does he who is a professor of mathematics, a great mechanical and electrical engineer, the greatest inventor of all times, keep his physical as well as mental powers?

To begin with, Tesla, who is by birth a Serbian, comes from a land inhabited by races.

His family tree abounds with centurians. Accordingly, Tesla—bearing accidents—fully expects to be still inventing in A.D. 1960. But the chief reason for his perpetual passion for intellectual frugality, Tesla has learned the great fundamental truth that he who only eats all of his bodily ills, but actually eats themselves—these do too much or too little by food that does not agree with them. With the hope to find that tobacco and black coffee interfered with his physical well-being, he quit both. This is the simple daily meal of the inventor.

**Breakfast:** One to two pints of warm milk and a few eggs, prepared by himself—yes, he is a bachelor.

**Lunch:** None whatsoever, as a rule.

**Dinner:** Celery or the like, soup, a single piece of meat or fowl, potatoes, one or two other vegetables; a glass of light wine. For dessert, perhaps a slice of cheese, and inevitably a bit of fruit.

**Tesla** is very funny and particular about his food but he eats very little but what he does eat must be of the very best. And he knows how much of him by his great inventor in science he is an accomplished cook who has invested his most dainty dishes.

His only vice is his generosity. The man who, by the ignorant unthacker has often beard, I have never been able to find how many millions of dollars was made over a million dollars of his inventions—and Tesla has kept them all. But Tesla is an idealist of the highest order and he is of men whom self means but little.

---

(Continued on page 743)
Subways of Down-Town New York

T he down-town section of lower New York, including the financial or banking district in the vicinity of Wall Street, offers an excellent opportunity to make a thorough study of the various electrically operated tram and subway systems, as well as of the engineering and technical features connected with these. This section is dotted with, or passes through, some of the most thickly populated districts anywhere in the world. Here office buildings rise twenty to thirty stories in the air, while the heavy steel trains rumble along thru the bowels of the earth under these gigantic business structures day and night. Fortunately for New York that it has a very solid foundation, as it is doubtful if all the ambitious subway and other arteries of travel now in operation and contemplated, could be operated with any degree of safety without the aid of mechanical equipment. The accompanying illustration, courtesy is due to the engineers of the Public Service Commission, who have supplied the necessary information concerning the various subway routes here illustrated, several of which are now under construction and not yet in operation.

In looking at this illustration of down-town New York, the well-known "battery loop" section is shown at the bottom, the top of the illustration being north, the bottom south, and the right and left—east and west respectively. The insert map shows the various underground systems including the Hudson Tubes under the North River, as well as the Pennsylvania Railroad Tunnels under the North and East Rivers. Beginning at the west side of the illustration and looking thru we come to the new West Side Subway, sometimes referred to as the 7th Avenue Subway. This is a two-track under-ground system running under the 9th Avenue Elevated Railroad, as becomes apparent. A down-town train moving toward the Battery, on the West Side track, passes under the loop on the "A" track, and after it has past the Battery Subway Station, goes down an incline so as to reach two levels underground, thru a tunnel which passes under the East Side Subway (which runs on Broadway in this district) and comes out on the up Subway at the older one, and the second arrow "A" indicates. Right here we have one of the most unique and clever bits of subway engineering imaginative, for this two-track system fulfills two important functions.

Firstly, and as just explained, it serves as the return loop for the trains of the West Side Subway. Secondly, the inner track of this battery loop, or track "B," is used to return the local trains of the East Side Subway (which runs on the other way Subway), and by following the inner or "B" track around the loop, by means of the dotted lines, it will be seen that the downtown or local trains run thru the complete loop, and eventually swing around on to the north-bound local track. The two center tracks of the East Side Subway are dotted with the other press tracks. As the dotted lines convey, these trains dive downward two levels and pass thru the 1st Avenue, the Brooklyn Bridge Tubes, one of the tubes carrying traffic thru to Brooklyn, and the other the trains returning from Brooklyn to New York. The East Side Subway is the older one, and the one that visitors are most familiar with and until recently,—when the change was made to the subway shuttle service between the Grand Central station and Times Square, due to the opening of the West Side Subway—this route of the East Side Subway trains was northward from the Brooklyn Bridge terminus along Fourth Avenue, to Park Avenue, Grand Central station, thence northward under 42nd Street, then northward along Broadway, etc. At the present time, owing to the change caused by the shuttle service, the effect between the Grand Central and Times Square stations, these trains make a turn to the eastward, at Grand Central station, and then proceed northward along Lexington Avenue.

The next subway of interest is the new Tri-boro Subway, which is often referred to as the B, R, T, Subway, but the official subway system of New York, the "Tri-boro Subway System." These trains will come from Brooklyn thru two new under-river tubes shown in the illustration, and proceed northward under 42nd Street, then northward under the East Side Subway, as the illustration clearly shows. The most southerly point of operation at the present time, is the Whitehall and Nassau-Broad Streets Subway. This remarkable engineering feat is taken care of by means of two interlocking two-way switches in the subways, etc. At this point, and, of course, a very elaborate system of interlocking switches and signals has been provided in order to prevent any accident, as may have happened in the past. This must be said to the credit of the New York Subway System, that there have been very few accidents, and these were very slight, incidentally. Some of the more accurately conceived electric safety systems are in use, whereby one train cannot pass into the next "block" while it is still occupied by another train.

At present the two westerly under-river tubes leading to the Tri-boro Subway at the Battery, a mile and a half north, and the two easterly branches are dead-ended a short way underground, in the vicinity of the Construction Shaft.

The William Street Subway will soon be completed and connected with the West Side Subway, running across the Park, and shall be called the Tri-boro Subway System. This tunnel takes its name from Clark Street, Brooklyn.

In this illustration, the several modes of travel available in New York City are vividly shown by the trains, cars or trolley cars which run along the various streets, as well as under the elevated railways. In the Battery district, here illustrated, the 6th Avenue Line, with the underground elevated tracks shown close to the street, is one of the finest examples of the system, and is a very popular train with the residents.

A similar plan is followed in the operation of the 2nd and 3rd Avenue "L" lines, as the illustration indicates. Thus two lines run as a single system from the Battery "L" to the 9th Avenue. This route is only a short way underground, and the numerous tunnels, which is just above the Battery Station. A similar plan is followed in the operation of the 2nd and 3rd Avenue "L" lines, as the illustration indicates. Thus two lines run as a single system from the Battery "L" Station up to a short way into the 9th Avenue, and then switches into two distinct lines of traffic. From this point elevated system runs along 2nd Avenue and the other along 3rd Avenue.

WHAT IS AN ENGINEER?—ASK UNCLE SAM

Especially interesting, from the standpoint of the war, is the publication of a new definition of the engineer which has been written by A. H. Krom, director of engineering, United States Employment Service, Chicago. The definition comes as the result of many queries that have originated thru a confusion of engineering terms and standards now in general use. After serious study and consultation with the various engineering authorities, Krom prepared the following definition:

"An engineer is one who economically directs man power and, by scientific design, utilizes the powers of nature for the benefit of mankind."

In writing this definition, Mr. Krom has sufficient space to offer a practical definition that will be of real value to technical men and to employers of technical men. The definition will doubtless be useful in clarifying the ideas of students of engineering and prominent scientific authorities declare that Mr. Krom's definition will give the public a true engineering ideal and that it covers all classes of engineering. In view of the importance of the engineer in the present war, it is especially important that his status be properly defined.
A Comprehensive Semi-Sectional View of the Battery Section of New York City and Its Multifarious Modes of Travel, Including Subways, Elevated Lines, Surface Cars, and Ferry-Boats. This Represents One of the Most Thrively "Subwayed" Sections of Any City in the World, and There are As Many As Four Levels of Passenger-Carrying Railways in Operation At Some Points. This View Shows the 6th and 9th Avenue Elevated R.R. Lines On the West Side, and the 2nd and 3rd Avenue Lines Running As a Single System In This District Down to a Common Station At the Battery. At This Point There is a Large Subway Station for the Local Trains of the "East Side" (Old Broadway) Subway, These Local Trains Returning Around the "B" Track of the Loop to the Up-Town Track. The Express Trains Drop Down Two Levels Underground and Dive Thru the Two Under-River Tubes to Brooklyn. The "A" Track of the Loop is Used to Return the Trains of the "West Side" Subway to the Up-Town Track, As the Dotted Lines Indicate. These Trains Use the South Platform of the Battery Subway Station, Which Is Not Shown Here. The Many Other Interesting Problems Which Are Being Engineered At This Point, Are Clearly Explained In the Accompanying Article.
THE MILKY WAY

By ISABEL M. LEWIS
OF THE U.S. NAVAL OBSERVATORY

The Galaxy or Milky Way defines in the heavens the position of the fundamental plane of the visible universe and the equatorial belt of the celestial sphere. Our own sun, attended by its planet family, is but one of the innumerable stars that stream to and fro in paths as yet undefined in form, but lying closely confined to the galactic regions and apparently controlled by the strong gravitational forces that exist therein. In fact all celestial objects, whether stars, nebulae or star clusters, are influenced by the Milky Way and as a result either crowd closely toward it or seek to avoid it so far as possible. Among the objects that particularly favor the Galaxy are to be counted the helium or blue stars and the hydrogen or white stars. The giant red stars known as the type N stars are found almost exclusively here as are also the stars that appear to form the connecting link between stars and nebulae—the Wolf-Rayet stars. Here also are to be found all the gaseous nebulae, all the temporary stars, except those that have appeared in spiral nebulae, and all the loosely-formed groups or clusters of stars, such as the Hyades and the Ursa Major group, which includes Sirius and the brighter stars of the Big Dipper.

The average width of this equatorial belt of the celestial sphere has been placed at approximately twelve thousand light years, according to most recent investigations, while its diameter is now known to be at least three-hundred thousand light years in extent. Outside this central segment, but symmetrically distributed with reference to it, lie the vast compact systems known as the globular star clusters. These limited in number to less than one hundred they are composed individually of thousands, if not hundreds of thousands, of stars far superior to our own sun in size and brilliancy. The spiral nebulae, to be counted by numbers running into the hundreds of thou-

Taken by Barnard with the 3.4-Inch Lens of the Bruce Telescope Temporarily Located on Mt. Wilson, Cal. This Photograph Shows the Great Star Clouds of the Milky Way in Sagittarius. It is in This General Direction that the Center of the Entire Galactic System is Believed to Be Located.

The photographs were made through the 24-inch reflector of the Yerkes Observatory in Wisconsin, and show the region of the great spiral nebula of Messier 82 in the constellation of Leo. The nebula is seen against the background of the Milky Way, and the photograph is taken in the light of hydrogen and oxygen.

Star Clouds in Sagittarius. Photographed by Mr. Barnard of the Yerkes Observatory. This Covers a Field of About Twenty Degrees.
The hazy, milky light of the Galaxy is a familiar feature to all who have seen it at its best over sea or prairie on a moonless night of early fall, spanning the heavens in a glorious arch of awe-inspiring beauty. With the aid of the most powerful telescopes the nebulous background is resolved into innumerable individual points of light, each representing a star of the universe, a sun attended possibly by planet-worlds of its own. The impression one receives of dense clouds of stars is due, it is believed, to the great extent of the galaxy in the fundamental plane rather than to an actual crowding together of the stars. The Milky Way is known to be extremely intricate and irregular in form. It encircles the heavens in the form of a great circle, but its width varies from twenty or thirty degrees in some parts of the heavens down to barely five degrees in others. For nearly one-third of its circumference it divides into two branches. In the constellation Argo in the southern hemisphere, it separates into several branches cross by dark lanes that in one portion of its path nearly sever it completely. Still further south, in the vicinity of the Southern Cross, is the noted Coalsack, a huge opening in the midst of dense star clouds. The dark markings that are such a characteristic feature of the Milky Way are due in some instances to actual breaks in the star formations thru which it is possible to gaze into the immensity of space beyond, in others to the presence of dark absorbing matter that intercepts the light from the more distant star strata. There are numberless examples of such dark nebulae intermingled with vast star formations and luminous gaseous nebulae. There are all gradations in these dusky markings from an inky blackness to the greyish tinge produced by a feebly glowing nebular light. The form assumed by the star streams of the Milky Way is still unknown. There is no clue to the structure of the whole in the infinite variety of its intricate formations. No two portions of the Galaxy are alike. There is no way of determining the relative distances of the various star clouds when even the nearest are immeasurably distant. It is the comparatively recent investigations of the globular star clusters, which have been found to be symmetrically arranged with reference to the plane of the Milky Way, that have furnished a clue to the great extent of the Galaxy in the central plane of the visible universe amounting to a distance of approximately three hundred thousand light years, a value far greater than any previously assigned to celestial distances. Within six thousand light years of the central plane and fairly evenly distributed above and below it, are to be found nearly all of the stars so far catalogued, including all the naked-eye stars and, in addition, all the irregular and planetary gaseous nebulae. In Fig. 1 is shown a section of the celestial sphere made by a plane perpendicular to the plane of the Milky Way. The crosses represent the positions of some of the globular star clusters projected upon this plane. The equatorial section, A-B, is twelve thousand light years in width and three hundred thousand light years in diameter. Midway between its upper and lower limits lies the plane of the Milky Way the pole of which is at P. C marks the center of the entire system and the globular clusters are distributed symmetrically with reference to this point. The center of the black dot, S, defines the position of our solar system in the Milky Way. The small black dot has a radius of about 1,500 light years. Within a sphere of this radius with a center at the sun lie all stars and nebulae with parallaxes greater than two thousandths of a second of arc. Therefore within the black dot lie all the stars and nebulae, the distances of which have been determined by direct means, that is practically all the stars visible to the naked eye, in cluding such well-known stars as Capella, Vega, Antares, Polaris and, of course, Sirius and Alpha Centauri. Even the most massive stars of the Galaxy, thousands and tens of thousands of times more luminous than the sun, appear blended in indistinct milky light at the distance of C. Only the great telescopes break this misty light up into minute distinctive points of light of the sixteenth or seventeenth stellar magnitudes. These stars form the characteristic star clouds of the Milky Way and it is readily seen from the diagram why one receives the impression of great star density when gazing in the direction of C, from the position of the solar system at S, tho the actual star density may be nearly uniform.

Women Now Trained as Meter Readers

Can women read electric meters satisfactorily? They can. Even when the meters are located in the darkest cellars. All of which has come to pass because the government had indicated that industries must help produce the needed additional military man power, and a Chicago electric light company has begun to train and employ women as meter readers. To train these new employees a temporary meter readers’ school in charge of the foreman of meter readers has been opened. The equipment consists of chairs and tables, an exhibit of a number of meters and parts of meters, and a large model of a meter dial. This latter is used in meter reading practise, and examinations are held after the class has been thoroly instructed by talks accompanied by demonstrations concerning the construction and working of meters. Twenty or thirty changes are made on the large dial, each student marking down her record each time on a sheet of paper. These sheets are then collected and marked up by the instructor.

TORPEDO TURNS TO STRIKE SHIP

The case of the Norwegian steamer Sommerstad, which was sunk on August 12th off Fire Island by a recurring torpedo, as stated in the official report, has raised the question among experts as to whether the Germans have not utilized the American invention of radio or wireless-directed missiles of that character.

While there is nothing in the official report to indicate that the torpedo which destroyed the steamer took its eccentric course of passing the bow and returning to strike fatally on the port side by the use of radio power, it is not denied that such might be the case.

Secretary Daniels called in an expert when the matter was discuss at Washington. In the latter’s opinion there was nothing remarkable about the return of the torpedo.

He explained that there were well-known mechanical devices, such as the gyroscope, by which a torpedo could be made to go forward from the point of departure for a certain distance and then recurve, as in the present case.

Both the Army and Navy have investigated the directing of torpedoes by wireless from shore, and have found they can be directed just as well as the gyrooscope plan.

An electric lighting company in New Orleans, La., has devised a portable electric light attached to a long pole. The pole is pushed into the ground and the attaching cord connected to the nearest lighting socket. The light is used for illuminating gardens, tennis courts and lawn parties.

The greater efficiency of electric cooking and the consequent conservation of fuel was pointed out in a recent article in Electro-Technich and Maschinenbau. Cases are cited of bakeries in which, other factors being as nearly as possible identical, steam ovens used 0.19 to 0.21 kg. of coal per kg. of bread (i.e., 955 to 1,060 calories), while electric ovens used 0.39 to 0.42 kw-hr. per kg. of bread (i.e., 322 to 359 calories). The power consumption of the electric ovens was 90 kw. and 50 kw. respectively.

SCIENCE IN THE EVOLUTION OF BIG GUNS AND SHELL.

The view below shows one of the laboratories at Sheffield University with a number of the students at that well-known English institution studying closely the recalcence changes occurring in steel by means of the apparatus shown and which are thermally registered. So interesting and important is this particular branch of scientific work, that the King of England, who recently visited this University, was particularly impressed with the results obtained. He manifested great pleasure in observing how an elaborate chart of the changes taking place in the steel under heat treatment in an adjacent furnace, could be registered continuously by a form of tape recording machine working in conjunction with the split-second clock shown in the photograph.
Largest Electric Crane Lifts Complete Tug-boat

The world is fast beginning to realize that American-made goods are the best to be had, and, also that they are built on integrity, and will not collapse like the German character has with great accuracy. In the case of an accidental interruption of electric current, all of the crane's motions are automatically locked by means of brakes, and so ensures the impossibility of dropping the load.

The German Floating Cranes did for the Panama Canal. This "Made in America" crane is said to be the largest ever constructed in this country.

To give a more concrete idea of the amount of work this apparatus can accomplish it may be said that its capacity is equivalent to the weight of 100 of the largest touring cars. The empty lifting hooks weigh about two tons, or the equivalent of a large touring car. When the jib is raised to its maximum height it is over 200 feet above the water level, a height greater than that of an 18-story building. As previously stated, the whole structure is mounted on a flatboat, or floating pontoon, and must not be endangered by handling these immense loads.

The boat contains a complete boiler plant, and an engine driven generator which supplies the electric current for operating the various motions of the crane, which are controlled from a small house mounted high above the deck. By the means of a few levers and master controllers one operator is able to control all the functions with the utmost delicacy.

The speed can always be controlled by the means of the electrical mechanism of the crane. When heavy loads are lowered, the motors are turned into generators and thus the speed is controlled.

The Largest Floating Electric Crane Ever Constructed in America. It is 200 Feet High, and Has a 150 K.W. Engine-Generator Set.

Safety and accuracy are essential, as the crane is used to handle large guns and turrets on battleships, and if thru carelessness or inaccuracy these should be damaged, it would mean a loss of hundreds of thousands of dollars.

One of the illustrations shows the first work with the crane did. The navy tug Massasoit was suddenly sunk in one of the harbors. After divers had past the necessary cables under the tug, the crane rapidly and quickly lifted it to the surface, as shown.

The following data will give a good idea of the enormous size of this machine. Size of pontoon 140 feet long by 85 feet wide by 15 feet deep; size of engine generator set, 150 kw.; the crane has a main hoist consisting of two hooks of 75 tons each, fixed on the jib; an auxiliary hoist of 25 tons capacity movable up and down on the boom; the crane rotates in a circle, the rotating being controlled by two 60-h.p. motors; the boom lifts up and down from a practically vertical position to an angle of about 30 degrees from the horizontal in its lowest position; the lifting is accomplished by two 10-inch screws operated by two 60-h.p. motors; the main hoists can operate separately or simultaneously, as desired; when lifting the maximum load it is operated by two 60-h.p. electric motors; the auxiliary hoist has separate motors for hoisting and trolleying, each of which is 60-h.p. The counter-balance at the rear end of the crane is fixed and amounts to 600,000 pounds; the total weight of the pontoon crane (displacement) is 5,000,000 pounds; the capstans are electrically driven, four in number, one at each corner of the pontoon; the anchor hoists are steam-driven, two in number, one at each end. The main pivotal bearing, or step bearing supports a ball or universal joint and carries a maximum load of 2,021,000 pounds; the speed of the main hoist under maximum load is about 6 feet per minute; the speed of the auxiliary hoist is 20 feet per minute; the speed of the rotation is one revolution in four minutes; speed of lifting boom, entire range 12 minutes. The boom is of the cantilever type.

SELLING ELECTRICITY BY THE "CAN."

ELECTRICAL Main February, 1919

W e of this generation are quite familiar with the method of supplying kerosene and gasoline by the "can," but who ever heard of selling electricity by the can? But such an arrangement promises to come into vogue in Chicago, where the new "metering can" here illustrated has recently been developed and perfected. It has been protected by United States patents issued to Mr. E. O. Switzer, of Chicago, Ill., and the various details have been practically all worked out, including the design of the metering element for direct current as well as alternating current service. Owing to the abnormal conditions resulting from the great war, it was not deemed advisable to try to put this device so far on the general market, but now that peace conditions are with us, the concern who has developed this remarkably simple device are getting ready to place it on the general market. This "metering can," as it may be called, is intended to take the place of the conventional watt-hour meter, or kilowatt-hour meter, especially for small current consumers, where it is firstly—quite expensive to install a watt-hour meter, and secondly, considerable expense is incurred on the part of the operating company, by having these meters read by professional meter-readers every month. When these metering units have become available, all Mr. Householder will have to do will be to go to the electric light company or their agents, and purchase several of these cans. These he takes home and uses one at a time as necessary. The apparatus works on the electrolytic principle, a certain amount of metal being acted upon by the passage of the current thru it, and after a certain number of hours the metal will have been sufficiently eaten away to open the circuit.

The measurement of current depends upon the electrolytic action of a small copper cylinder of known weight, this being gradually disintegrated by electrolytic action during such time as the current may be used to light lamps or operate motors, etc., but is unaffected during the time when no current is being used. The electrolyte used either for D. C. or A. C. is a saturated solution of copper sulfate. These metering cans are arranged to give a warning signal so that the householder will know ahead of time when he should replace one of the units with a new one. The accompanying photographs show how the metering can is plugged into a wall receptacle in a very simple manner. The meter can here illustrated is so constructed as to be enclosed in a metal case, as to remove all chances of tampering with it or derangement by accident.

As aforementioned, the can is provided with a projecting contact arm which is inserted in the keyhole of a switch box. It is then given a slight twist to engage the contact with the spring clips of the main circuit and left there until the predetermined amount of current has been consumed. Truly it may be said that this device will mark a new era in electric service to the public.

NEW ELECTRIC FURNACE REGULATOR.

The device is installed easily, and when once in operation relieves the householder of all of his cares in relation to the furnace except the merely mechanical process of "putting on coal." The time clock arrangement makes it possible to maintain a low temperature during the night, and at the time set in the morning, opens the drafts and increases the temperature to the point desired.

This device consists of a thermostat with a clock attachment which operates a motor in the basement, which, in turn, regulates the drafts and dampers of the furnace. Two types are provided, one for use in houses already wired for electricity, and the other in which two dry batteries supply the impulse from the thermostat to the motor box, and a spring motor operates the drafts and dampers.

In the type used in houses already wired the alternating current motor is connected to the alternating main house wires. A transformer on the bottom of the motor box steps the 110 volts down to 6 volts, for use on the thermostat circuit. Thus the dry batteries are dispensed with. The diagram shows clearly how the regulator works. The thermostat may be set at the heat desired and it will keep the room in which it is installed at that temperature, because if the temperature falls the motor in the cellar will operate sufficiently to open the drafts and increase the heat. The reverse is true when the temperature rises. The thermostat should be installed in a room as near the center of the house as possible and should not be in such a position that its action is subject to the effects of drafts from doors and windows opened for only a moment. — (Photo courtesy W. E. Co.)

Automatic Electric Regulator Which Tends the Furnace Drafts for You. It Comprises a Thermostat, Clock, Motor and Battery or Other Sources of Current.

A mong the hundreds of new devices and appliances published monthly in the Electrical Experimenter, there are several as a rule, which interest you. Full information on these subjects, as well as the name of the manufacturer, will be gladly furnished to you, free of charge, by addressing our Technical Information Bureau.
ELECTRICAL

AN ILLUMINATED SERVICE FLAG FOR HOME AND STORE WINDOWS.

An enterprising electrical concern of Milwaukee is now offering the device shown in the accompanying illustration, known as the "Honorlite," which is made in a form to take the place of a military service flag. The device consists of a handsome indestructible wood pulp pedestal with two modelled eagles holding a flat alabaster globe, which is 8 inches in diameter. A 3-by-5 inch service flag is shown on one face of the ball, while five blue stars are furnished loose and can be attached to the circumference or face of the ball as desired. This decorative device stands 12 inches high by 6½ inches wide at the base, and is wired with 6 feet of cord and plug. It is pointed out by the maker that this device is one which can be used for other purposes, such as special advertising and as a special window display.

A NEW "INDUCTOR" TYPE MAGNETO FOR AUTOS.

This new auto and motor-boat ignition magneto is of the inductor type, which means that the coils in which the current is induced are stationary, and the revolving part or rotor consists merely of a block of laminated steel. Instead of horseshoe magnets, as always used in the conventional type of magneto, this magneto employs straight bar magnets, which are accurately ground and securely clamped to top and bottom yokes. The bottom yoke forms a pole piece extending nearly half way around the rotor tunnel, while the top yoke has two poles, one carrying the windings or coils, and the other serving as a magnetic by-pass. The magnetic circuit is shown diagrammatically in the two accompanying sketches. In one the rotor pole is shown opposite the pole of a top yoke which carries the windings or coils, and with the rotor in this position, the maximum flux passes thru the coils. In the other sketch the rotor is shown opposite the end of the magnetic by-pass, and in this position all of the magnetic flux passes thru the by-pass and none thru the coils. As the rotor has two poles, the flux thru the coils passes thru a maximum and a minimum twice during every revolution of the rotor.

As all coils and current carrying parts are stationary, there are no slip rings or brushes, except the brush in the distributor. The distributor gears, of bronze and steel, are of ample dimensions, and in connection with the rotating member of the current distributor, are carried in steel and bronze bearings, the sleeve of which is cast integral with the front die casting. The base and top yokes are made of gray iron, and are tied to the die-cast end plates by screws. They are located in place by dowel pins. The field structure is bored and ground as a unit, thus insuring thoroughly accurate alignment of the yokes and poles faces. The stationary coil, condenser and laminated pole piece are assembled as a unit and mounted integral with the top yoke.

This new inductor magneto gives two sparks per revolution. The spark characteristics are said to be such as to give very effective ignition, the current rising suddenly to substantially its maximum value at the beginning, and being well sustained. One feature that distinguishes the spark obtained from this type of magneto compared to that obtained from other magnetos, is that it passes thru the gap of the spark plugs always in the same direction. That is to say, the same part of the spark plug is always positive.

AN ELECTRIC "MOVIE" MACHINE FOR THE PARLOR.

A new type of moving picture machine for commercial, educational and home use has just been brought out by a New York concern.

Its special features are electric motor drive, by a motor that can be used on both direct and alternating currents; high illumination, and a feed mechanism that gives practically perfect results.

Motor drive was used on the older types, but it was necessary to have separate motors for the different kinds of current, and this naturally limited the use of the motor driven machines. The new motor used here, however, operates at practically the same speed with either kind of current. Hence this machine can be used wherever there is electric light.

The illumination is provided by a 14-volt, 2-ampere, argon-filled, high efficiency light, that is sufficiently brilliant for throws as long as 100 feet, and for pictures up to 12 feet wide. The 110-volt current received from the lighting circuit is reduced to low voltage for the use of the lamp, by means of a rheostat; this rheostat is adjustable, so that the degree of illumination can be varied to suit conditions.

The film-moving mechanism is of the intermittent type and is of a novel design. The manufacturers claim that this projector projects an absolutely flickerless picture.

This machine is safe to use since it can take only slow-burning films, the standard celluloid film being unusable in it. Many hundreds of these special films have already been made up; special subjects can be made up as desired, and standard films can be copied on to the special stock.

The weight of the machine is 23 pounds and it is arranged for packing in a carrying case similar to a small dress suit case.

India has increased its annual coal production to 12,000,000 tons and is introducing electrical machinery into some mines.

An electric alarm clock which awakens deaf sleepers by jarring their beds has been invented in Germany. They need it.

A NEW ELECTRIC HORN SWITCH.

Something new in the way of an electric horn switch or push button, for Ford cars, has been recently put on the market. It is attached to the throttle lever by means of two small clamps, and therefore is always within reach of the hand without an extra movement.

You Have Often Wished for a Small "Movie" Machine for the Parlor—Here it Is. Its Universal Motor Operates on Alternating or Direct Current.

The device is a tube-shaped cylinder about ½ inch in diameter and 3 inches long, which contains contact point and wiring, which are cemented in place to insure durability and safety from dampness. The connection is made to the regular equipment by cutting in on the main wiring on the post.
Amateurs Win Questionable Victory

By H. GERNSBACK

Pyrrhus, when congratulated by his friends on the occasion of his victory over the Romans under Fabri-cius—but which cost a terrible slaughter of his own men, threw up his hands and exclaimed: "Yes, but one more such victory, and we are done for!"

attempted any nation wide movement to secure the defeat of the bill in question, save and only the Electrical Experimenter. At this very time a few thousand letters, no concentrated effort was made to appraise the entire radio fraternity as was done by this publication. About 50,000 letters were mailed out to all radio amateurs interested, and the response we know has been nothing short of wonderful. The writer was in receipt of thousands of letters from amateurs, who in turn in concert with their friends had protested vigorously to Washington, with the result that the amendment printed elsewhere in this issue came about.

Not only that, but the press was also appealed to as well, and many papers publish comments and express themselves in no uncertain language about the drastic and entirely unjustified measure known under the title of H.R. 13159.

The surprising thing however was that none of the other technical publications—there were only two of them commenting about the bill at all—had the situation right in hand. One publication which professes to have the interests of the amateur at heart did not even know that there was such a thing as the Padgett bill! Not one
Alexander Wireless Bill—Amended

65TH CONGRESS, 3D SESSION, H. R. 13159.

IN THE SENATE OF THE UNITED STATES, December 11, 1918.

Referred to the Committee on Commerce and ordered to be printed.

AMENDMENTS.

Intended to be proposed by Mr. Watson to the bill (H. R. 13159) to further regulate radio communication, viz.: On page 2, after line 8, add the following:

"The word amateur, or private, station shall be construed to mean any radio station operated by a citizen of the United States for the benefit of himself and science, and which does not employ commercial radio communication."

On page 2, line 14, insert the words "private or amateur before the words "technical and training schools stations.""

On page 2, strike out section 3 and in lieu thereof insert the following:

"First. The wave length of private or amateur stations shall be from one hundred and fifty meters to two hundred and twenty-five meters.

Second. The Government shall have the right to stipulate that the power used by private or amateur stations shall not be greater than five hundred watts as measured in the antenna circuit, except by special license and shall not be greater than two hundred and fifty watts as measured in the antenna circuit, except by special license, within one hundred and fifty miles of any seacoast, lake front of the Great Lakes, or coast of the Gulf of Mexico.

Third. The Government shall have the right to prevent all persons below the age of fifteen years to use, operate, or own any sending outfit or to engage in the receiving of radio disturbances into the ether.

Fourth. The Government shall have the right to require all private or amateur stations to be licensed, and failure to procure a license shall be punishable by a fine not exceeding $600.

This is wholly satisfactory in all respects. It would give the twenty-five to more meters to operate on than he has now. The present wireless law confines the amateur to 200 meters.

We can see no fundamental objection against this.

"Fifth. The Government shall have the right to require all owners or operators of private or amateur stations to pass an examination whereby the operator of such station shall be able to receive ten words a minute before said operator may be licensed to operate any sending station.

"Sixth. Private or amateur station operators shall not be permitted to operate unmanned sending outfits of greater capacity than two hundred and fifty watts as measured in the antenna circuit, except by special license, within the territorial limits of the United States.

This restriction to us seems to be too severe. We should like to see 15 K. W. inserted instead.

We see no fundamental objection to this, except that it seems rather mysterious to us why regulations should require an examination to pass ten words a minute. What good does the receiving do him? Perhaps the framers of the bill meant "send" not "receive."

Object most strenuously against this unjust measure. There is no necessity for licensing receiving stations only. Our jewelers, thousands of them scattered all over the country must have receiving stations to receive accurate time from Arlington and the like. Not many would want to be licensed under this measure. Secrecy in wireless is impossible anyway. If anyone must receive signals he can do so very readily and easily anyway, law or no law. Important messages are never sent out by the Government or commercial companies unless they are in code. On top of this the present wireless law already has penalties for divulging contents of messages.

"There is no occasion or necessity for such a drastic measure at the present time. It is not justifiable to take the present antidote which has been carried on for the last month in Washington, the thousands of protest letters sent to Senators and Representatives, as a fair indication as to how the wind blows, we think we are correct in saying that the temper of the statesmen in Washington may not be such as would support legislation of this kind at this time.

We might write volumes why amateurs should not be supressed, but we believe that official Washington today understands the situation fully. They know by this time what service the amateurs have rendered their country, and how many thousands of expert operators were recruited into the Army and Navy at the outset of the war. Congress will surely not blot the amateurs out of existence in recognition of their work, particularly when there has not been advanced one single, solitary, good reason why the amateur should not be allowed to pursue his innocent endeavor.

America, the greatest democratic country in the world, the one that cherishes the highest ideals of any nation, is not going to start in at this late date to take away the liberties of hundreds of thousands of loyal citizens who have already proved their worth, and will do so again.

In printing the amendment to the Alexander bill below, we call particular attention to paragraph 13. This constitutes nothing but a joke, for the bill below becames a law, and if the Navy Department was in power, it could very readily and without any trouble whatsoever prohibit the sending of messages, let us say, between the hours of 5 P.M. to 1 A.M. This, in the language of the bill, would be "definite periods of the night or day."

If we would have a law, let us have a law without "ifs" and "buts". Paragraph 13 is entirely too elastic in favor of the Government and would inevitably result in shutting the amateurs out at the slightest pretext.

There are certain things in the amendment which are undoubtedly satisfactory to everyone, but as a whole, we are not in favor of the measure. It is too autocratic, particularly the clause whereby it would be necessary for amateurs who had receiving apparatus only to secure licenses. Not one in a hundred would wish to go to the trouble of obtaining a license for very obvious reasons. It has been found in the past, that wherever an amateur had to obtain a sending license, it was done most reluctantly, and it was the cause of keeping thousands of amateurs away from wireless. It would work even more disastrously if every receiving station were to be licensed. Most of the jewelers—who receive time by this method—would not operate receiving outfits for the word, "Government License", to many simple folk means a big undertaking, and in many cases when a young man finds out that he must obtain a Government license in order to have his wireless sect, he prefers to be without it.

What good is it anyway to license a receiving wireless station? If a record of amateur stations is wanted in Washington why not let us insert a clause in the bill which would make it compulsory for every manufacturer or seller of wireless apparatus to give a list of the amateurs buying such instruments, which to all intents and purposes would be the same thing as licensing and thus frightening the amateur. This system was in vogue during the war where it became necessary for all manufacturers to supply a list of radio sales to the Navy Department.

No manufacturer would object to this, we are certain, and as the government would then have the list of names it would work out the same without discouraging thousands of amateurs.

The Alexander bill, amended, follows with our comments in parallel columns:

(Continued on page 735)
President Wilson Always in Touch with Washington—via Radio

For several days, going and coming in completing his mission to the European peace conference, it was and will be necessary for the President to administer the affairs of Government from the high seas. Unique as this situation is, hardly less so were the preparations made to enable him to keep in communication with the world during the voyage.

What is considered the most powerful wireless system ever installed on any ship is that carried by the steamer "George Washington." A corner of the wireless room, fitted with the latest radio devices, is seen in the accompanying picture.

Special arrangements never before used were made for handling President Wilson's wireless messages and to keep him in constant touch with Washington.

This announcement was made by Secretary of the Navy Daniels in connection with a statement that the Navy Department was in continuous communication with the "George Washington" and the battleship Pennsylvania on their trip from New York.

Means were at hand whereby he could be brought instantly into communication thru the powerful radio station at Abpoeon, Md., and Arlington.

Mr. Daniels said:

"The George Washington and the battleship Pennsylvania are both equiped with the most modern radio apparatus, some of which was installed for this particular trip.

"This apparatus includes, on the Pennsylvania, the most powerful transmitting set on any United States naval ship and also special receiving apparatus for receiving from high power stations used ordinarily only for transatlantic messages. The George Washington was also especially equiped with similar receiving apparatus. On board both ships were installed radio telephones and the newest type of low power sets. These only in communicating from ship to ship. The George Washington and the Pennsylvania were thus able to communicate with each other and at the same time receive messages from shore.

"All messages for the President were sent by the new naval high power station at Annapolis, which is five times as powerful as the Arlington station. These messages were received by the George Washington and the Pennsylvania simultaneously. All replies were forwarded from the George Washington to the Pennsylvania and then instantly relayed to shore by the Pennsylvania.

"At three special naval radio receiving stations, one in Maine, one in New Jersey and one in the Navy Building, Washington, expert operators listened continuously for the Pennsylvania's messages. The messages when received were forwarded with utmost despatch to the transatlantic radio division of the office of the Director of the French high power stations forwarded messages direct to the ships. The President was thus kept in touch with Washington and Paris or London simultaneously, for the George Washington easily received the messages sent from the Annapolis station until the end of the voyage and the ship was in Brest, France."

The first Cabinet meeting in all history, directed to a certain extent by wireless from mid-ocean, was held in the White House on December 10th, with Vice-President Marshall officiating in the President's absence.

A wireless message from the George Washington asked Vice-President Marshall if he would preside and the latter assumed his temporary duty as acting President.

President Wilson was in constant communication with the United States and France during his entire voyage from the United States to France thru the Pennsylvania's powerful radio transmitting and receiving sets. The Annapolis high power transmitting station, transmitting on 16,000 meters, the high power transmitting set at New Brunswick, N. J., transmitting on 13,000 meters, the high power transmitting set at Tuckerton, N. J., on 9,200 meters and the high power radio station in Lyons, France on 15,500 meters were used for communications to and from the President.

The President on board the U. S. S. George Washington was conveyed by the U. S. S. Pennsylvania (which is the best equiped ship aloft for signaling purposes in regard to radio communications) and five torpedo boat destroyers. The Pennsylvania's radio equipment consisted of the following apparatus: One 30 kilowatt Federal arc transmitter, which was used for transmitting messages to the United States and France on 3,000 meters, one 10 kilowatt Lowenstein spark transmitter, transmitting on 600 and 952 meters, which was used for intermediate communication with low power coastal stations; one short range radio telephone transmitter, transmitting on 207 meters and one vacuum tube short range transmitting set, transmitting on 450 meters, which were used for intercommunication between the Pennsylvania and U. S. S. George Washington.

The Pennsylvania transmitted messages direct to the United States up to a distance of 2,500 miles. Communications with (Continued on page 743)
THE Harvard Radio School has developed hundreds of expert radio operators for the United States Naval Service, and a group of them are here illustrated practicing with one of the portable wireless outfits which landing parties use. It is surprising how quickly they can erect an aerial mast and connect the various instrument cabinets together with the dynamo, ready for instant service. It is all a matter of discipline, the commanding officer will tell you. Discipline and system whereby each man does a certain thing, but does it well. That in a nutshell is the whole secret of Uncle Sam's naval efficiency. These men are trained to perform their duties with clock-like precision, and each move in erecting the wireless set here shown is done identically the same each time, which is the only way that real speed can be obtained. Unlike the German system, Uncle Sam's boys are trained not only to do a certain thing in a complex task and to do it well, but they are each and every one of them educated and carefully instructed on all the details governing the operation and functioning of the complete radio outfit. Thus in an emergency any one of these radio men can do anything from tapping the key to erecting or disassembling the gasoline engine driving the dynamo, in the event that it fails to work, and ascertain just what the trouble may be. It has been a great task to train all of these thousands of radio operators in the various complex branches of the art, but Uncle Sam's radio instructors, both naval as well as civilian, have proven their worth.

345 MARCONI RADIO STATIONS BOUGHT BY U. S. NAVY DEPARTMENT.

All of the American Marconi radio stations, except the four high power plants, have been bought by the Navy Department, a Washington dispatch of December 5th stated. At the same time it developed that the department purchased the great Sayville station recently from the Alien Property Custodian along with the Marconi purchases. The American Marconi company relinquishes the field of handling ship to shore messages.

The purchase includes all Marconi coastal stations, nineteen of which are situated on the Atlantic and Gulf coasts, sixteen on the Great Lakes, and ten on the Pacific coast. The four high power units which the company still retains include the Belmar-New Brunswick station in New Jersey, for transmission of messages to England; Chatham-Marion, Massachusetts to Scioodonia; Marshall-Bolinas, California to Hawaii; and Koko Head-Kahuku, Hawaii to Japan. Two units represent each station, each about fifty miles apart, one being utilized for transmission and the other for receiving.

In taking this station the United States is merely following the lead of other nations in controlling the ship to shore business. England took over these stations on her coast 12 years ago, and since that time they have been operated by the Postal Department. The same applies to France, Italy, Germany and countries in South America. Brazil has always operated her coast radio stations.

An official of the company points out that the cream of the business in the future will be the transatlantic message traffic. The ship to shore business has been rapidly forwarded, and with the exception of a few ships the private business aboard ships or to them has never been large. At the same time development of the transatlantic business is going forward, and when the Government relinquishes control of these big stations, they undoubtedly will produce big results for the company.

The price paid by the Government is not announced at this time although it has been definitely settled. The Government has also purchased from the Marconi Wireless Telegraph Company of American wireless apparatus on some 300 ships now under Government control. An announcement to that effect was recently made by Edward J. Nally, vice-president and general manager of the company.

The sale of apparatus to the Government Mr. Nally said, is "the first result" of a change in the company's policy whereby "it will in the future sell as well as lease wireless apparatus."

A recent London dispatch quotes Godfrey Isaacs as saying that the Marconi Company would outfit airplanes employed in air passenger and mail service with wireless and would supply operators in the same way as it now serves ships. It is also intended to receive regular reports on air conditions in different localities and to circulate these for the information of the pilots. As every airplane will have either a name or distinguishing number, it will be possible to send telegrams from any part of the world or from any ship to an airplane. It is intended that this organization will be ready by the time the peace is made.

Arrangements recently have been made for the erection of wireless stations in the extreme parts of China, one on the frontier of Cashmere, and another on the Chinese side of Siberia. Mr. Isaacs has arranged with Handley-Page for the transport of the necessary machinery by one or more of his big machines. The journey will take two or three days in place of the same number of months.

NAVY MODIFIES RADIO RULES.

Naval conditions in the North Atlantic are such now that restrictions upon commercial radio communications are being removed, according to an official announcement. Personal and commercial traffic with naval vessels as well as with merchant vessels is now permitted west of the 40th meridian.

The restrictions upon land wire telegrams addressed to naval personnel on board naval vessels, which caused such telegrams to be forwarded thru the Bureau of Navigation, have been removed, and it is now permissible to address personal telegrams direct to men on naval vessels in an American port. Restrictions on amateur wireless stations have not been lifted.

Vacuum Valve Action and the Electric Current

By K. G. ORMISTON, ASSOC., I. R. E.
RADIO INSTRUCTOR, HEALD'S ENGINEERING SCHOOL, SAN FRANCISCO

Nearly all text-books on physics and electricity state that the direction of the electric current in the terminal of the source of pressure to the negative terminal. The average radio student, from the time he first takes up the study of electricity, is taught that the positive pole of a battery or dynamo is in a state of high pressure and the negative pole in a state of low pressure, and that the direction of the electric current is from positive to negative. This conventional theory is quite satisfactory until the vacuum valve and its action is considered; then the confusion begins.

Figure 1 represents a vacuum tube with the filament heating circuit and plate circuit. (The grid is omitted as it has no bearing on the present discussion.) The positive terminal of the battery B is necessarily connected to the plate P. In studying the action of this circuit the radio student is asked to believe that the current in the plate circuit flows from the positive terminal of the battery to the negative terminal; that is, from positive to negative within the tube, in spite of the fact that the ELECTRON STREAM IS FROM THE FILAMENT TO THE PLATE.

In this connection the leading text-books make the following statements:

1. "Using the ordinary convention for the direction of the current flow (which is opposite to the direction of flow of the electron stream), we say that a current flows from the plate to the filament." 2. "It will prevent confusion . . . if the student understands that inconformation with the old theory electricity FLOWS IN THE DIRECTION OPPOSITE TO THE FLOW OF THE ELECTRONS."

3. "The number of electrons drawn from F to P per second, that is, conventionally the current from F to P, is found to be roughly proportional to the square of the field intensity."

The instructors in a certain Government Radio School are in their efforts to "conform with convention," even go so far as to teach that positive ions flow from the battery B to the plate P to neutralize the negative electrons discharged from the filament to the plate, and thus endeavor to show that a current actually flows from positive to negative. But these instructors fail to explain how positive ions, WHICH ARE ATOMIC IN SIZE, can flow freely thru a copper conductor or a vacuum!

It is my personal experience that much confusion is caused by the lack of a better understanding of vacuum valve action, as well as certain other phenomena, is gained if the radio student is taught from the start that the electric current is in reality a flow of negative charges, or electrons, from the negative (high potential) to the positive (low potential) pole of the source of E.M.F.

The above statement concerning the direction of the electric current is not a theory; it is a conclusion drawn from experiment. That the electric current consists of a movement of ELECTRIC CHARGES can readily be shown by the following simple experiment.

In Figure 2, P is an insulated metal plate. G is a sensitive D'Arsonval galvanometer, connected between the plate and the earth. The simple circuit of the galvanometer is shown in the accompanying diagram. The terminal plate is connected as shown, with the zinc or negative terminal of the cell connected to the same side of the galvanometer as the metal plate P. R is a gutta-percha rod, which is held in the hand and may be electrified by rubbing with cat's fur. The gutta-percha rod, which is negatively charged, will become negatively charged. When the charged rod is moved near the plate P, the galvanometer will deflect in a certain direction, let us say to the right. The deflection of the galvanometer is caused by an electric current passing thru its windings, and the current must consist of negative electric charges.

Negative charges may be repelled from the plate by the presence of the negatively charged rod, and flow thru the galvanometer to the cell. These charges may be attracted from the earth and flow to the plate. In either case, it is the flow of electric charges which produces the effect of an electric current. It would be expected, when the charged rod is removed the galvanometer deflects in the opposite direction, that is, to the left. Only if the rod R were to electrify the plate P will either the negative charges which were driven from the plate to the earth, return to the plate, or releases the excess of positive charges which were repelled to the plate and pass off to the earth.

During the first part of the experiment the key K has remained open. Now place a heavy shunt on the galvanometer, so that the current from the simple cell cannot damage the instrument. Then close the key K. The galvanometer will deflect TO THE RIGHT. Note that the deflection is in the same direction as when the charged rod was made to approach the plate P, and therefore either negative charges are flowing thru the galvanometer from A to B or positive charges from B to A. We can now draw this conclusion: The electric current consists of either a stream of negative charges flowing from the negative terminal to the positive terminal, or a stream of positive charges from positive to negative, or possibly both.

The smallest possible electric charges, both positive and negative, have been isolated in the electron microscope and other scientists, and their mass and velocity are definitely known. The smallest charge is negative in sign, that is, it shows the same characteristics as a gutta-percha rod when electrified to approximately 1/1800th the size of the smallest atom (hypothetical atom). The smallest positive charge is found in the atom which has lost one or more electrons, and is therefore atomic in size. This smallest positive charge, which is but an atom deficient in negative electricity, is called an ion.

It is evident that the positive ion cannot act as a carrier of electricity in a solid medium, or in a vacuum, on account of its size which must be at least as large as the smallest atom. But the electron, bearing the negative charge, can easily pass between the atoms of a solid conductor.

From the experiment of Figure 2, we conclude that the so-called electric current consists of a stream of electric charges, either positive or negative. Thompson's measurements show that the positive charge cannot flow (in the media with which we are dealing); therefore, we may state that the electric current is a movement of electrons (negative charges) from the negative pole of the source of pressure to the positive pole.

For further proof let us again consider the vacuum tube circuit. We have a circuit connected to the battery B, made up of copper conductors and the space F—F, which is devoid of all matter. The electron A is an atom that an electric current flows in this circuit. Since no ponderable matter exists in the vacuum tube, the only possible carriers of electric charges within the tubes are electrons. The filament F is heated to incandescence in order that ionization will take place, and electrons will be emitted from it. It is necessary, in order to have any current at all in the plate circuit, that the positive pole of the battery B be connected to the plate P, so that the negative charges (electrons) will be attracted to the plate rather than repelled from it. With the arrangement of Figure 1 there will be a stream of electrons or negative charges flowing from F to P within the tube, and it follows that the current in the plate circuit indicated by ammeter A must consist of the movement of electrons from the NEGATIVE pole of battery B to the POSITIVE pole.

Let us not be hampered by "convention" and "old theories," but endeavor to seek the Truth. Then Progress will be assured.

THREE GOOD "HOOK-UPS" FOR A SMALL RECEIVING SET.

Four instruments are needed for this simple receiving set, and all are of the "K. I. Co." make. They are, one small tuning coil, one miniature detector, one sext condenser and one pony telephone receiver. In the diagrams, which are self-explanatory, A is the aerial; G the ground; T.C. the tuning coil; M.D.—miniature detector; F.C.—sixth condenser and P.R.—pony receiver. With a suitable aerial and ground system, you will be surprised by the good work this little set will do. It is interesting to try the different "Hook-Ups" to find which works best in your locality.

HOW TO LEARN THE INT’NL CODE ABBREVIATIONS.

The attached drawing is that of a rotating dial to be used in quickly ascertaining the definition of the various International Radiotelegraphic Abbreviations. Such as:

QRA? What ship or coast station is that? QSA? Are any signals strong?

As shown in the drawing the bottom or larger disc is made stationary to a wooden base and upon it the various definitions are printed above the QR’s and below the QS’s, so that when the smaller disc, firmly held by the rod holding the handle, is rotated in alignment with the letters of the alphabet, the definitions are indicated thru the slot cut in the rotating disc.

EFFICIENT GALENA DETECTOR.

Everyone is sure to have a small piece of brass rod for which he can find no use. The hard rubber top to an ink bottle in connection with a brass cap from an old dry cell forms a cup. A garage will give you all the slightly worn ball bearings you can use and you need but two. If you have never broken a ruler with a brass strip in it you are a wonder. A few screws, a nut, a couple of binding posts and a piece of board or fiber and you have the makings of a good detector. The accompanying illustration tells the rest. Once you have the tension screw, all you do is hook her up and with a second’s adjustment (which won’t knock out) in come the signals fine and clear.

NOVEL BUZZER PRACTICE SET.

In the drawing (A) is a key of any type, mounted on a board as shown. (B) is a buzzer of high pitch. (C) is a coil of wire which is wound non-inductive; an inductive coil will not work. This coil may be made by using 50 feet of No. 24 insulated wire, doubling it and winding it double, starting with the loop end. Why this is done need not be explained here. (D) are the battery binding posts, and (E) are for the phones. A 75 ohm resistor will work fine.

A HANDY ADJUSTABLE CONDENSER.

The feature of this condenser is that the capacity units are stationary and therefore least apt to get out of order; the switch element only rotates. The builder can make the condenser of any size desired. The case is made of hardwood, sandpapered and varnished in the usual way. This condenser has been found suitable for every kind of work where an adjustable capacity is employed. The scale is read thru an index window attached to the moving switch blade.

DEAD-END SWITCH.

The ends of coil units are brought to switch points, one on each end of wire, (1, 2, 3, 4, 5, 6, 7). Note the fiber or other insulating plate, carrying at the under edge brass strips (C) which, when disc is turned (by knob B) connects the switch points over which the strips lie. D is a brass strip which makes contact only with outside row of points. Suppose (D) were on point 5. Then the pairs 1, 2 and 3 would be connected, but 6 and 7 would be entirely out of circuit, because (D) touches only the outside switch point. D connects to ground.

The Vortex Ring Theory of the Electron

By F. W. RUSSELL and J. L. CLIFFORD

The discussion of the various theories of matter is one of the most important problems that confront the scientist today. Chemistry, Physics, and nearly all branches of science hinge upon this question. The atomic theory has been thoroughly established, but

They claim that the electron is nothing more or less than a minute whirl in the ether, or as we shall call it an ether vortex ring.

When Lord Kelvin brought forward about 1870 his famous vortex ring theory of the atom, the scientific world hailed with them the same material with which they issued from the box, and seemingly possess elasticity of form. Altho many interesting phenomena may be observed using this simple form of apparatus, for accurate and detailed experiment the liquid ring apparatus, described below, will be found the more practicable.

The first requisite is a glass tank at least 30 inches long by 12 inches wide and high. A gold fish aquarium will answer the purpose, provided it conforms to the dimensions. If an aquarium is not available, a tank may be easily constructed by making a box with the base of wood and the sides of glass plates. This box should be well coated with asphaltum in order to make it water tight. When the experimenter has provided himself with a suitable tank, the next problem which confronts him is the construction of the "gun" or projector with which to generate the vortex rings. An efficient gun may be easily manufactured from odds and ends to be found in any experimenter's laboratory. As may be seen in the drawing, Fig. 1, the two principal parts of the gun are the liquid container and the electric agitator. At one end of the liquid container, which consists of a round tin box, is fastened a diagram of the ultimate structure of the atoms is still an open question. The leading theories of today make use of smaller particles called electrons to form their hypothetical atoms. These particles were first discovered by Crookes, and about 1897 were definitely proved by Weichert, and Sir J. J. Thomson, to be negatively charged particles traveling with the enormous velocity of nearly 180,000 miles per second. In addition it was found that these particles had an extremely small mass. In fact about one eighteen-hundredth the mass of an hydrogen atom, the smallest known atom. The presence of these particles was again proved by the disintegration of Radium, and even an electric current is now believed to be a flow of these electrons. The electron then is one of the most important entities in the world today, and yet there are very few theories as to the nature of the electron. The physicist has side-stepped the problem in the past by simply calling it a hard negatively charged corpuscle, but what a hard corpuscle is, is left to the reader's imagination to picture. Lately, however, the new school of French physicists have brought forward the theory which seems most complete and astounding delight this tangible explanation of the structure of the atom. Upon the discovery of the electron, however, the vortex atom theory was thrown into the background and into obscurity. Since the new theory of the electron has been proposed, however, it is interesting to repeat and discuss the experiments with smoke and liquid rings performed by the experimenters wishing to prove the vortex atom theory.

The simplest form of apparatus needed to produce rings of smoke is a round cardboard box with a small aperture in one end. If the box is filled with smoke or with fumes of Ammonia and Chlorid formed by the action of Ammonia and Hydrochloric Acid, and the opposite end tapt sharply, rings of smoke will be projected from the box and will hold their shape for some time. The rings move swiftly forward, carrying with

Phosphor-Bronze sheet or other flexible substance. In the opposite end, which may be the cover to the box, a small hole about \( \frac{1}{8} \) of an inch is cut, care being taken that the sides of the hole are smooth in order to insure perfectly formed rings.

Here We See the Actual Vortex Ring Apparatus Set Up in the Authors' Laboratory.
The box should be made water tight. As may be seen in the drawing the agitator consists of a strong electric bell with the gong removed, and the leads taken directly from the coils. The bell should be well impregnated in paraffine or other insulating compound so that it may be submerged without danger of short circuit. The bell should be so placed that the striker will strike the diaphragm of the diaphragm, a hollow blow when the magnets are energized. The best position for the striker can only be determined by actual experiment.

When the projector has been completed, if the experimenter wishes to use red colored rings, the liquid container should be filled with Sodium Hydroxide and Phenolphthalein. Be sure that all the air has been expelled, as any air in the container causes the rings to be irregular. The gas is then lowered into the tank, and the magnets energized by means of batteries, controlled by a telegraph key. Rings will be seen to issue from the aperture, and traverse the length of the tank intact. If the water is slightly acidulated with Sulfuric Acid the rings will immediately disappear upon breaking up. If the experimenter wishes to make milk-white rings, an emulsion of Silver Chlorid can be used that will become colorless in a weak solution of Ammonia. To make such an emulsion a tablespoonful of gelatin should be dissolved in about a liter of hot water. About 15 grams of Silver Nitrat previously dissolved in water should be added. Then stirring well, add a weak solution of Hydrochloric Acid until the Nitrat is all precipitated as a chlorid. This milk-white solution should be diluted with equal parts of water before using. Rings of this solution shot out into a weak solution of Ammonia, will hold their form until broken, and will then completely disappear. The amount of current necessary for each gun can only be determined by practice, and the nature of the rings wished. After some practice, the key can be so manipulated, as to produce swiftly, or slowly moving rings. Two guns should be constructed, as it is necessary in some experiments to connect them in series, and shoot rings towards each other. The guns should be so arranged on handles that it is possible to shoot rings from all angles under the water. When the guns have been adjusted and the tank filled, the experimenter is ready to begin on his experiments.

The kinetic energy of these rings is considerable, as shown by several rather interesting experiments. If a light ward chain be suspended in the path of a ring it will be noticeably deflected by the impact of the ring striking it, altho the ring itself is by no means changed. A layer of light paper is tightly stretched on a frame, and held in the path of the rings, the rings will break thru the paper, but in turn are broken up by the impact. A pretty experiment is to similarly stretch a piece of chiffon cloth and hold it before the gun. The rings will pass thru it without being broken or disturbed in their motion.

If two guns are placed opposite each other, and rings be projected simultaneously, it will be observed that if they strike each other fairly, both will be broken up. If, however, their path is such that they would merely have touched on their edges, they will bend out of their course and will pass each other without injury. This phenomenon of the mutual repulsion of the rings is in accordance with the modern idea of the electron; namely, that they are like charges of electricity, which repel each other. These vortex rings, of course, are not supposed themselves to have any electric charge, tho acting like an electron; they are simply clever illustrations of what an electron is supposed to be.

If a ring is shot towards the surface of the water in the tank, it will be noticed that at certain angles, it is reflected from the surface and continues on a new path the same as the angle of incidence. At other angles the ring will not be reflected but will jump out of the water with a spurt. Besides this it can be shown that these vortex rings can be refracted. The tank should be half filled with water, and a dense solution of Sodium Chlorid siphoned into the bottom of the tank, so as to D the streamline of the liquid outside the aperture will be somewhat as is indicated by the full lines. After the liquid has issued from the aperture it would be expected that the liquid would move as the broken lines indicate. Instead it bends into spirals, each particle moving towards the place where the pressure is diminishing, and the ring formed continues to rotate around a circular center.

TESTING THE QUALITY OF MILK.

By means of two simple tests if it is possible to determine with a reasonable degree of accuracy the quality of milk. A qualitative test to show whether the milk contains water or not is made in the following manner: Take a perfectly clean steel hatpin and immerse it point down into the milk. If on withdrawing it a film of milk covers the same, there is no free water present. On the other hand the presence of water in small quantities will prevent the milk adhering to the pin.

Should the above test show the presence of water the percentage of the same can be obtained in the following manner: Take an ounce of plaster of Paris and wet it with the milk under test till a smooth paste is formed. Allow the paste to dry, determining the length of time that elapses before it hardens. The percentage of water can then be obtained from the following table:

<table>

ELECTRICAL February, 1919

"Ball Lightning" Experiments
By SAMUEL S. WEISIGER, Jr.

In the January, 1916, issue of the Electrical Experimenter you publish a discourse on "Ball Lightning" and gave instructions for the experimental production of it. Thru the kindness of Mr. Porter, Instructor in Physics at the Allegheny High School, I have been able to make the several photos accompanying this letter. Under each photo there is given a short description of the circumstances under which each discharge was made and the phenomena connected therewith.

In making these photos a 75,000 volt Toepfer-Holst static machine was used. The distance between the sharp metal points was from 5.5 to 6 centimeters. This distance must be found by experiment, and although it is absolutely essential to have the correct distance between points, it will nevertheless differ with the capacity of the static machine.

Much trouble will be encountered if the sharp points, used to produce the discharge, are not free from grease and highly polished. The best way to polish the points is to take a little powdered chalk (blackboard chalk which has been scraped to a fine powder with a knife) and put it on some kind of cloth and turn the point of the electrode, at the same time giving considerable pressure to the cloth where the point is being turned. The best connection for the electrodes was found to be obtained by means of two brass chains.

Two large-sized, sharply pointed damaging needles suitably mounted form admirable electrodes. It is practically impossible to use blunt needles.

There will be much trouble in finding the correct spacing for the electrodes and it will probably require some experimentation. In any case the spacing is dependent on the power of the static machine.

Some Trouble Was Encountered in Getting this Spark-Ball to Form. Evidence of This Is Shown By the Plate Being Exposed By a Tiny Charge Or Burst of Light On One Side of the Negative Electrode. The Uneven Course of the Spark-Ball Is Clearly Defined.

When the plate is put under the electrodes be sure to get the emulsion side up, as the discharge occurs better when the plate is placed in this manner. When the plate is under the electrodes and the static machine has been started, the spark ball should form very quickly. After the ball has detached itself from the electrode, turn the machine very slowly in order to expose the plate longer. The rate of travel of the spark ball is proportional to the speed of the static machine.

Should the machine be stopped before the spark ball reaches the other electrode, the plate will only show the path of the ball to that point.

Knowing that there is considerable interest in these "Ball Lightning" experiments we have republisht below the original directions for producing ball lightning in the laboratory as outlined by the famous French scientist M. Leduc. His experiment makes possible the production of a slowly moving globular spark not easily obtainable in any other way, in so far as we know.

To produce this imitation ball lightning it is necessary to employ two very fine metallic points, each of which is in connection with the positive and negative poles, respectively, of a static machine of small or medium size. These globe as it travels is quite slight, it taking from one to four minutes for it to traverse a path of six centimeters in some cases, and before reaching the positive electrode the globe bursts into two or more luminous balls which individually continue their journey to the positive electrode. On developing the photographic plate (which, of course, should be placed under a ruby light while the foregoing experiment is conducted) there will be found a trace on it of the exact route followed by the spark globe—the point of explosion, the routes resulting from the division, and the effluxium around the positive electrode point. Also, if one should stop the experiment before the globule's arrival at the positive electrode, the photographic plate will only show the route to that point. The fireball takes for its course the conductor, which apparently short-circuits the static machine. If sulfur or some other powder is thrown on the photographic plate while the experiment is being conducted, and also while the ball is moving, its path will be marked by a line of ares, looking very much like a luminous rosary.

[The Editors will be glad to hear from any of our readers who have made experiments in this direction. Photographs are particularly welcome.—Ed.]

HORSE-POWER OF WIND MILLS

This Is One of the "Freak" Ball Lightning Discharges. The Spark Ball Formed At the Negative Electrode and Travelled Straight For the Positive Pole, But Did Not Reach It. It Disappeared Without Exploding. The Machine Was Kept Going and for Some Unknown Reason Another Ball Formed and Backed Away From the Negative Electrode, and Broke Into Two Pieces Before It Reached The Positive Electrode.
A USEFUL ELECTRICAL LABORATORY SWITCH-BOARD

By H. DANNER

A SWITCH-BOARD is a valuable accessory to any Experimenters electrical laboratory. The switch-board here described is intended for use on an alternating current circuit of 110 volts, 60 cycles frequency. But if the switch-board is to be used on a direct current circuit the only changes necessary are the substitution of D. C. instruments and the removal of the low voltage transformer.

The marble or slate panel is 3 ft. 10 in. long, 2 ft. 6 in. wide and 1 or 1½ in. thick. It is supported by two angle iron uprights, 2 x 2 inches, and 6 ft. 4 in. long, plus four inches which is bent back at a foot as illustrated in Fig. 4. To make this bend saw off one side of the angle four inches from the end and after heating it red hot at right angles by putting it in a vise. Use a hammer to make a square bend. The panel is fastened to the angle iron by six ¾ inch bolts as shown in Fig. 1. The weight of the marble or slate is supported by a piece of angle iron across the bottom of the switch-board fastened as shown in Fig. 5 (a bolt can be used instead of a rivet). The top of the board is braced to a wall by means of a flat piece of iron bent on one end to permit it being bolted to the wall.

A marble drill should be used in drilling the marble, but an ordinary drill will serve the purpose. Water will help to drill either marble or slate.

We are now ready for the instruments and switches. The voltmeter is preferably a Weston model 151, 0-150 volt scale range. The ammeter is the same model, 0-150 amperes scale range. Both instruments are 9½ inches in diameter. All connections are made at the back, conforming to standard switch-board practice.

The main line cut-out is of 100 amperes capacity and is located between the instruments. The main line switch, 100 amperes, connects to the bus-bars to the line. The ammeter is connected in series with the switch (see Fig. 1). The voltmeter is connected to a small, double-pole, double-throw knife switch, one side of which is connected across the main bus-bars and the other side across the step-down transformer outlet.

The upper set of ½ inch bus-bars are ¾ x ¾ x 24" and are spaced two inches apart. The bars leading from the main line switch to the second set of bus-bars are of the same size. The lower or second set of bus-bars are ¾ x 6/4 x 24".

The bus-bars are fastened by No. 8-32 copper or brass machine screws (½" in diameter). All connections must be well made. The bars are insulated by bending them up and over the other bars. The switches are connected to the bus-bars by short pieces of copper bars.

The upper row of switches consist of two 60 amp D. P. S. T. switches placed in the center and two 30 amp D. P. S. T. switches on each side. All the switches have fuse clips attached of proper capacity.

The four switches in the lower row are 15 amp D. P. S. T. switches.

Below this row are placed three plug receptacles, two polarized and the other unpolarized, located as shown in the drawing. A double-pole double-throw 15 ampere switch is placed in the middle with a small charging rheostat on the right. This switch connects the storage battery to the motor-generator and to the discharge outlet. The plug receptacle on the right is connected directly to the motor-generator and affords a source of direct current. The one to the left of the switch is connected to the storage battery and is of use in many experiments. The plug on the left side is connected to the step-down transformer.

The service to which the individual switches are put depends upon the needs of the experimenter. The two 60-amp switches are intended for the arc, electric furnace, or for a 5 K.W. step-up transformer and other apparatus requiring over 30 amperes. The switch for the arc is connected to the stage plug at the bottom of the switch-board. A variable resistance is connected in series with the stage plug.

The first switch on the left-hand side, second row, connects the primary of the step-down transformer to the line. The next switch to the right is for a high voltage transformer. Then comes the hand wheel or knob of a small field rheostat for the motor-generator. The field rheostat is mounted behind the board in such a position as not to interfere with the other apparatus. To the right of this comes the motor-generator switch, and on the right is the switch for the lights.

The transformer slide at the lower left-hand side consists of a ¾ square brass rod 14½" long. Over this rod a ¾ square hollow tube, 1 inch long is fitted, with a handle and spring contact large enough to cover only one contact point at a time. The contacts can be made from ¼ round brass rod and fastened and connected in the same manner as starting box contacts.

Use your judgment in all of this work. There (Continued on page 753)
Experiments in Radio-Activity

By IVAN CRAWFORD

- PART II—Ionization (Continued)

In the first installment the construction of a super-sensitive electroscope was outlined, and the conduction of electricity thru gases partially discussed. Before going further into the mysteries of radio-active phenomena it is fitting that further experiments with this electroscope should be given. Another method for the detection of ions will also be given.

The retardation which an alpha particle experiences in its course thru matter, depends entirely upon the atomic weight of the atoms thru which it passes. Bragg and Kleeman found that the retardation of the alpha particle was approximately proportional to the square root of the atomic weight of the substance. In the case of metals, their weight per unit area, required to completely overcome the alpha radiation, is proportional to the square root of their atomic weight.

It was found that the retardation of the alpha particle by complex molecules was an additive property. For, consider that a molecule is composed of N number of atoms of atomic weight W, together with N' number of atoms of atomic weight W', etc. Then the retardation of the alpha particle is \( N \sqrt{W + N'} \sqrt{W'} \).

Sir Ernest Rutherford has determined the specific retardation of alpha rays in metals both by observation and calculation. A few of his results with the commoner metals are given below: s is the observed stopping power of the atoms in terms of air as unity; \( w \) is the atomic weight. It will be noticed that the quotient \( s / \sqrt{w} \) is approximately equal in all cases.

By a series of simple experiments the reader may determine the retardation of alpha particles by thin sheets of the commoner metals. On a grounded metal disc a quantity of radium bromid is placed. See Fig. 1. Thin sheets of aluminum, brass, copper, iron and lead should then be interposed between this active material and the electroscope. The discharging current should then be measured as outlined in the previous paper. The sheets of the various metals should be of the same thickness to allow comparison. It is noticed that the experimental results will compare very favorably with the calculated values.

A very interesting experiment is to interpose successively various thicknesses of aluminum between the radium bromid and the electroscope. With the electroscope charged, a gold leaf past over five divisions on the scale in 412 seconds. The time with uncovered radium bromid was 15 seconds. Upon placing a sheet of extremely thin aluminum leaf over the ionizing agent the electroscope discharged in 25 sec., showing that a portion of the alpha radiation was stopped by the aluminum leaf. When a sheet of aluminum foil about .001 of an inch thick was interposed, the electroscope was discharged in 137 sec. A sheet of aluminum .01 of an inch thick cuts off the entire radiation, and the ionization caused by beta particles, which easily penetrate this obstacle, is very small, discharging the electroscope in about 380 sec. A sheet of lead cuts off the entire radiation, the electroscope discharging the same as when empty.

To determine the retardation of alpha particles by aluminum the following experiment was performed. The radium bromid is covered by successive layers of aluminum leaf and the discharging current measured in each instance. For radium the ionization falls off in geometrical progression as the thickness of the aluminum is increased. Thus, as Maloney has shown, where \( I \) is the intensity of the active substances uncovered, then \( I = I_0 e^{-\frac{a}{t}} \), where \( e \) is the base of the Naperian logarithms and \( a \) is an absorption constant which has a different value for each substance. It is proportional to \( s \) in the preceding table. This law holds true for homogeneous radiations, but when using ordinary radium bromid, any ionizer, four sets of rays are given off, each having a different penetrating power. Until the thickness of the aluminum is great enough to cut off one set of rays, the law given above will hold true. The author has found that about 6 thicknesses of aluminum are sufficient to cut off the first set of radiations. In the accompanying graph Fig. 2, the full line indicates the successive stopping powers up to 6 thicknesses of aluminum leaf for radium as determined by Rutherford. These results were obtained by the author and experiments by the reader should be proportional to these.

That the radiums given off by radio-active materials ionize the air into positively and negatively charged carriers can be readily proven by the following experiment: Connect a spark gap with an induction coil and with a vacuum tube as indicated in Fig. 3. A large Geissler tube will give excellent results, the larger the better. The spark gap should be capable of fine and delicate adjustment. The coil must not give too strong a discharge, but the discharge must be very steady. Arrange matters so that the coil gives a steady discharge at the spark gap and then draw the electrodes apart until the discharge just passes thru the vacuum tube, only an occasional spark crossing the gap. A small quantity of radium bromid is then brought into the vicinity of the spark gap. When this is done the Geissler tube will be partially dimmed and the discharge will pass by way of the spark gap. The greater the amount of radium bromid used the more the tube will be dimmed. This is caused by the ions formed by the radiations from the active radium bromid. If care is taken that the conditions named above are secured the experiment will always be successful.

(To be continued)
A NOther valuable feature that the lathe possesses is the cutting of tapers. Standard tapers are rated at the amount with which the diameter changes in a foot of length. We will take as an instance the standard Brown and Sharp taper, which is one-half inch per foot, and how it is turned in the lathe.

First, it can be turned by the use of a taper attachment on the saddle of the machine, or else by offsetting the tail-stock from its regular central position to give the tool for cutting the prescribed taper. The second method of offsetting the tail-stock is not as simple as the first. If the distance of the center points enter the work, or the mandrel is ignored, the mandrel length can be considered as the distance between the centers. In order to determine at what length the centers shall be offset for a given taper, a simple arithmetical calculation will be required. This is done by multiplying the length of the work or mandrel in feet by one-half the required taper in inches. To turn a Brown and Sharp taper, on a piece of work nine inches long, the problem would work out in the following manner. This particular calculation refers to the one-half inch taper per foot specified in the opening paragraph of this lesson:

\[
\frac{9}{2} \times \frac{1}{12} = 0.1875 = \text{3/16 inch.}
\]

The value of 3/16 inch would be the required amount necessary to offset the center of the tail-stock. The off-centering is accomplished by unscrewing the set screw on the base of the tail-stock and shifting it towards the cutting tool 3/16 inches away from its original center-line position. Fig. 3 illustrates the simplicity of accurately figuring the exact position of the respective centers by the use of a steel scale or rule. It will be noticed that in the above illustrative problem that both the length and amount of taper are given. However, at times it happens that the amount of taper is not given. Let us suppose that a piece eight inches in length is to be turned on one end. The taper portion should be four inches in length. The difference in diameters of this four inch section is to be one-half inch. The problem is, how much must the taper be offset? If the taper is 3/4 in 4 inches, it would be 1/2 inch in a foot or three times as great, and the tail-stock would be moved over one-half of 1/2 inches or 3/4 inch. This calculation holds good were the piece a foot long, but as it is 8 inches, or 3/4 of a foot, the tail-stock should be moved over 3/4 x 3/4 or 1/4 inch. Should the piece be twenty inches long, the tail-stock would be moved 1/2 x 3/4, or 1/4 inches.

The above problem was assumed for simple calculation, the lathe centers merely touching the ends of the working piece, thus making the length of the piece the same as the distance between the centers. In actual practise the depth of the centers in the work must be considered. The calculation must be so as possible to avoid continually changing the tail-stock in order to get a reasonably good taper fit. The necessity of considering the exact distances depends somewhat upon its length. If the piece is very long the actual taper will differ considerably from the calculated taper. If each center point is 3/4 inch, then we would enter a total of 3/4 inch. The length of the piece should thus be reduced by 3/4 inch in the calculation. While turning the taper, the calipers should be used frequently so that it may quickly be determined whether or not the tail-stock is correctly placed for the job in hand.

In order to test the accuracy of the taper as it is turned it should be prest lightly into a steel bar and worked back and forth sufficiently to mark the places where bearings points occur. If the work has been lightly covered with some marking pigment (chalk), the bearing points will be more distinct. However, care must be taken that the coating is not too heavy, as it will be liable to deceive the amateur. Adjust the taper setting until a correct fit is obtained. Another very good method of testing the exactness of the taper is to obtain another taper mandrel or form of standard size, having the same taper pitch, and placing its surface against the one cut, as shown in Fig. 3. If the two tapers can be the standard. Then set a pair of calipers on one side, and run over the entire surface with the same distance on the calipers. If no indication is shown of surface irregularity the taper is said to be true; if high or low marks are present, the taper is not true and a readjustment of the tail-stock setting is necessary to correct it.

In turning down a taper the centers must be employed. This work must be turned down with the aid of the face plate and dog shown in Fig. 3, which illustrates the position of offset work for taper cutting. A lathe chuck cannot be used for this class of work, as the piece to be turned down is kept rigidly in place in a central position, thus preventing its position from being offset. The chuck is used only when a taper attachment is employed. It should never be used otherwise. At times in cutting a very short taper or conical point and when a compound rest is at hand the compound rest is turned to an angle equal to the angle of the taper to be cut. However it is advisable to adhere to the simple method of cutting a taper and as soon as the novice feels quite safe with this method he will then be at liberty to try those more difficult.

The experimenter who is mostly familiar with the use of the lathe for turning concentric objects will now see that the lathe is just as useful in turning objects of eccentric shape. The most common of such objects is the eccentric which operates the valves of a steam engine. If the work has a hole thru it, as in the above example, the hole is first finished to the required dimensions and then a mandrel is used for carrying the work on the lathe centers. While the mandrel has been built on one set of centers exactly true with its axis, for concentric turning, it has a second set of centers which offset the amount required for the eccentricity specified. In the case of eccentrics made solid with the shaft, there are two sets of centers, one for turning the shaft—and the other for stabilizing the opposite end of the shaft. Fig. 4 shows how such an eccentric is arranged in the lathe for proper turning. Note the position of the central axis of the object with respect to the live and dead centers of the lathe. At certain times the specified eccentricity is too extreme to allow both pairs of centers coming within the limits of the diameter of the shaft. Special ends may be cast, forged (or clamped) on the ends of the work, and can afterward be machined off. In crank-shaft turning, special attachments should be provided for the ends of the shaft, or special chucks for the turning may be made to hold the work.

The turning of crank pins on shafts is (Continued on page 749)

Experimental Chemistry

By ALBERT W. WILSDON

Thirty-third Lesson

ARSENIC: History.

The ores of Arsenic, in the form of its two kinds, Realgar and Orpiment, were known to the Alchemists. Geber was familiar with the oxid, and Mangus refers to the metal; but Brandt, in 1773, first showed that white arsenic was obtained by burning the metal.

Like its salts it is poisonous when taken into the stomach. At a temperature higher than 180°C, it unites directly with most elements. It unites with metals to form arsenids, analogous to the sulfids.

Oxids.

Two oxids are known Arsenous Oxid (AsO₂) usually written As₂O₃ and called arsenic trioxid, Arsenic Acid, Arsenic, White Arsenic, etc., and Arsenic Oxid (As₂O₅). The former only is important, being the most important commercial compound of the element. From this other compounds of the metal are formed. It is a white substance, sometimes amorphous and sometimes crystalline which resembles flour when pulverized. It dissolves very slightly in cold water, upon which its particles seem to have a repellent action, but on boiling for a long time more dissolves. The best solvents are Hydrochloric Acid and Alkalis. With Hydrochloric acid it forms:

\[ \text{As}_2\text{O}_3 + 6\text{HCl} = 2\text{AsCl}_3 + 3\text{H}_2\text{O} \]

Salts.

There are two classes of salts, the -ate and the -ite, of which Sodium Arseniat [Na₂AsO₄] and Sodium Arsenit [Na₃AsO₃] are examples. In the former, the valence of Arsenic is 5, in the latter 3. The -ite salts are more frequently met with. The

\[ \text{As}_2\text{O}_3 + 3\text{HCl} = 2\text{AsCl}_3 + 3\text{H}_2\text{O} \]

There are four important tests, Marsh's, Reinsch's, the Carbonic, and the Hydrogen Sulfid. Besides these there are the modified Gutzeit Test, Bettendorf's, etc.

MARSCH'S TEST.—This is the most delicate and interesting, and consists in first forming Arsin [AsH₃], then decomposing it and subliming the arsenic. Any soluble arsenical compound in presence of nascent hydrogen forms Arsin, which is readily decomposed by heat, when the arsenic sublimes. By this process a quantity far too small for the most delicate balance, can be detected,—in fact a mere trace of the element.

Explanation.—Suppose the compound to have the composition Asₓₓ, in which X is any nonmetallic monad. Hydrochloric acid gives this reaction:

\[ \text{As}_x\text{X}_y + 3\text{HCl} = \text{AsCl}_3 + y\text{HCl} \]

Nascent Hydrogen decomposes AsCl₃ and combines with both elements.

\[ \text{AsCl}_3 + \text{H}_2 = \text{AsH}_3 + 3\text{HCl} \]

The Arsin passes out and is burned together with the excess of hydrogen.

\[ 2\text{AsH}_3 + 3\text{O}_2 \rightarrow 2\text{As}_2\text{O}_3 + 6\text{H}_2\text{O} \]

A Bunsen flame decomposes the Arsin.

\[ \text{AsH}_3 = \text{As} + 3\text{H}_2 \]

When the metal sublimes in the capillary tube. The question arises whether any other element than arsenic would act in a similar way. Antimony acts almost exactly like it, forming gaseous and combustible SbH₃, which likewise decomposes and sublimes as a metallic mirror. Several tests serve to distinguish the sublimed Arsin from Antimony, the best being the solubility of Arsin in Sodium Hypochlorit (NaClO) and the insolubility of Antimony. The quantity of Arsenic can be determined by comparing the depth of shading on the deposit with that of tubes containing a known quantity.

REINSCH'S TEST.—This consists of depositing Arsenic on copper, then oxidizing the Arsenic and subliming the As₂O₅ formed.

The compounds of Arsenic will first change to AsCl₃ by Hydrochloric acid. The copper in the heated acid will withdraw the arsenic and deposit it, leaving copper chlorit in solution. Heat will not sublimate the arsenic, which at the same time will combine with the oxygen in the tube to form As₂O₅, and this in turn will sublime as a white solid on the close sides of the tube. Identification is then made by examination under a microscope, when a portion of it

(Continued on page 750)
This department will award the following monthly prizes: First Prize, $3.00; Second Prize, $2.00; Third Prize, $1.00. The purpose of this department is to stimulate experimenters towards accomplishing new things with old apparatus or old material. Any useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best idea submitted a price of $1.00 is awarded; for the second best idea a $2.00 prize, and for the third best prize of $3.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings. Use only one side of sheet. Make sketches on separate sheets.

FIRST PRIZE, $3.00

AN ELECTRIC FLAG FOR THE LAPEL.

The materials necessary for this are: 3 feet of electric cable, a flashlight bulb, a flashlight battery, a small U. S. (or service flag) paper flag and some cardboard. Fix the cable as shown in Fig. 1, and then bend both wires on each end, as shown in Figs. 2 and 3. Make a cardboard box an inch larger each way than the flag and 3⁄4-inch thick. On the front cut out an oblong opening 3⁄4-inch smaller all around than the flag. Paste the flag over this. Contributed by FRANCIS V. SLAGT.

INTENSIFYING THE SHOCK FROM MAGNETOS.

Most people are aware that the "mag" out of an old-fashioned telephone makes a fine "shocker." My "rig" will increase its shocking capacity tremendously, as all who try it will be fain to believe.

Cut a piece of thin brass of suitable size to rest against the driving wheel when it (the brass) is secured to the base. No dimensions are given as the mageto-ringers vary in size. Contributed by L. G. S. TROREY.

SECOND PRIZE, $2.00

THIS MICROPHONE MAKES AUDIBLE THE FLY'S FOOT-STEP.

This microphone, when properly constructed, is capable of making audible the footfall of a fly, the drawing of a thread across the instrument, the slightest touch on the table on which it is placed, the blowing of one's breath on it, etc., etc. To construct this instrument first take a cigar box and remove the lid. Next hunt up a discarded alarm clock and remove the hair-spring. Secure a piece of wood, 4" x 3½" upon which to fasten the uprights, and a piece of copper sheeting or any other suitable metal for the uprights. Connect these as in the diagram. From an old flashlight battery obtain the necessary carbon. Paste the hair spring onto one upright, and the carbon to the other, first hollowing out a

THIRD PRIZE, $1.00

CONTACT POINT FROM UPHOLSTERY NAIL.

An ordinary upholstry nail is flattened with a hammer and a hole punched thru it with a set punch, as shown in sketch. The hole serves to thread and hold the wires. This is a cheap and practical contact point. Contributed by BERT O'LEARY.

WHAT MAKES THE PLATINUM RING HOT?

If a platinum ring (or even a piece of platinum wire) is warmed gently for a few moments and then suspended in a glass, having a small amount of alcohol in the bottom, the platinum will become red hot. The glass had best be covered with a piece of pasteboard having a hole in the center. The phenomena may be explained by the fact that platinum has the peculiar property of causing certain gases to condense on its surface. The condensation of alcohol fumes is so rapid as to cause the platinum to become incandescent.

Contributed by S. S. GARRETT.

SEWING MACHINE MAGNET WINDER.

Here with is illustrated a wire-winding machine which is easily constructed. Most all wire winding machines are turned by hand, but by using this scheme you can both wind faster and easier. The pulley of the machine is brought against the belt of the sewing machine and the same is caused to turn due to friction. Contributed by E. T. JONES.

This wire leads to other coils of mag. 53
A HOME-MADE GAS TORCH.

As I needed a gas torch I set about to make one. I first procured two pipes, one gallon can; the gas may be taken from the gas service pipes or from a carbide generator.

Contributed by HERBERT PEHRSON.

HINTS ON DRILLING GLASS.

Drilling glass is a difficult proposition and very few amateurs possess tools suitable for this purpose. The following apparatus will drill holes, varying in size from the smallest up to an inch or more.

First procure a brass tube the outside diameter of which measures the same size as the desired hole. Revolve this on the surface of the glass, either by hand or better by means of a small hand drill. The drilling must be started by allowing the lower end of the tube to be guided by a wooden block, with a hole cut in it the size of the tube. After the tube has past thru the glazing this guide can be removed. An excellent abrasive for this drill is emery dust and turpentine. It is an excellent idea to drill from both sides, since this results in a clean, smooth edge.

Contributed by PAUL G. EDWARDS.

COINS FOR WEIGHTS.

In an emergency, ordinary coins can be used as weights. The weights given in the following table are near enough for all the usual purposes.

- Dime weight ............. 40 grains
- Cent weight ............. 50 grains
- Nickel weight ........... 80 grains
- One-quarter Dollar weight 100 grains
- One-half Dollar weight ... 200 grains
- One Dollar weight ...... 400 grains

By simple addition and subtraction a great many different weights can be made with these coins. For instance, to obtain a weight of 20 grains, place a nickel on one side of the scales and a quarter on the other, and then add enough of the chemical solutions above to reach the load.

Contributed by HUGO J. ENGEL.

A RELIABLE HYDROGEN SULFID GENERATOR.

Here is a plan and description of a simple and cheap hydrogen sulfid generator.

This hydrogen sulfid generator has given very satisfactory service to the author. It can also be used for generating hydrogen, carbon dioxide, etc.

The necessary parts are:
1. Student lamp chimney.
2. Glass or porcelain jar (a large fruit jar will do).
4. Rubber stoppers, three hole and one plug.
5. Iron sulfid (FeS).
6. Hydrochloric acid (HCl).

Contributed by JOHN R. BUXTON.

THE PREPARATION AND USE OF BLUE-PRINT PAPER.

The following describes the manufacture of blue-print paper in terms that can be easily understood by any one. No difficulty should be experienced in either the making or the use of the paper.

In order that the best results be obtained it is necessary that good material be used. All vessels in which the solution is made must be kept clean and when not in use should have water in them as far as possible. Do not use soap when washing the trays, as the least trace will do harm to the solution.

Where ordinary work is to be done, any kind of well sized paper will answer, if tough enough to be washed. Different grades of unsensitized papers can be bought at engineers and photo supply houses.

The following formula is for a good solution that will give excellent results to the amateur; this solution is made up of two salts, dissolved in water and applied to the surface of the paper:

Solution No. 1.
- Ferrocyanid of potassium .... 1 oz.
- Pure or distilled water ...... 6 oz.

Solution No. 2.
- Ammoniocrat of iron ....... 1 oz.
- Pure or distilled water ...... 6 oz.

When solutions are to be used mix equal parts of 1 and 2 and filter thru cotton or filter paper. This solution we will call No. 3.

The solutions should be applied to the paper in a dark and dry room with a very subdued light just enough to barely see by.

Small sheets of the paper may be best covered by floating upon the surface of No. 3. This is done by taking a sheet by two diagonal corners and laying it gently on the surface of the solution. This method does away with the possibility of air bubbles forming.

One minute or less will be sufficient for sensitizing. Remove the paper by drawing over the edge of the tray to remove any surplus liquid and to prevent any solution from getting on the back of the paper.

Large pieces are best sensitized by taking down upon a smooth table with thumb tacks and painting the solution on with a wide camel's hair brush. Take care to get it on quickly and evenly. Dry the paper by hanging up by its corners to a wire so that it will swing free. Before sensitizing a batch of paper it would best be to make a trial sheet and print it. The solution may not be mixed properly or the paper may be too absorbent, in which case the solution will go into the paper and will not come out when washing the paper, causing the print to fade in a short time.

After the paper has dried hard and without the slightest trace of dampness it should be rolled up tightly in a tight (tin or cardboard) tube and kept in a dark and dry place.

Printing is the exposing of the sensitized paper to the action of a powerful light with the copy to be printed placed over the paper. The direct rays of the sun are best for printing, but the electric arc is nearly as quick and has the advantage of being always constant—regardless of weather.

The drawing, tracing or negative is placed in the frame next to the glass with the paper under it, having its sensitive side up. Exposure will vary from 5 to 10 minutes, according to the light and tracing. The correct time is only found by experiment.

After the paper is sufficiently exposed, it is taken from the frame and immersed in a bath of clean running water. A print should be washed for not less than fifteen minutes or it will fade when placed in the light.

Excellent prints may be made in the following manner: Slightly expose the print so that when it is washed the white lines are not clear but appear bluish. Take the print out of the bath and lay it on a table and sponge it with a solution made up of one part of sodium dichromate of potash and two gallons of water. The lines will come out pure white and the background an intense bluish. Wash print thoroughly and dry.

White lines may be added to blue prints by the use of a solution made of soda and water to which a small quantity of prepared chalk has been added to thicken it. This solution may be applied with a ruling pen. Engineers generally use a white, red or yellow pencil for making corrections.

Contributed by RUSSEL MERRELL.
Telephone Amplifier. (No. 1,280,556; issued to Louis Seber.)

A telephone amplifier providing a loud-speaking portable telephonic apparatus enabling persons with impaired hearing to satisfactorily use the ordinary telephone. The usual Bell telephone receiver is placed on one side of the cabinet in which there is an opening communicating with a microphone transmitter. The transmitter in turn is connected from a rheostat and battery as well as switchboard to a low resistance, loud-speaking telephone receiver.

Signaling Apparatus. (No. 1,280,210; issued to Fulton Gardner.)

An ingenious signaling apparatus comprising an electromagnet in a receptacle, together with a coherent form of armature, the whole arrangement operating an alarm bell when actuated by voice or other sound waves. It is intended for bank vault protection and the like. The sound waves impinge on the microphone which is connected with a battery and primary of an induction coil. The secondary of this induction coil connects with the electromagnet of the alarm in question. This electromagnet acts on an iron filing armature, causing the filings to cohere, and thereby closing the alarm bell circuit. A condenser is shunted across the bell in order to provide a more steady current by virtue of its charging and discharging action.

Telegraph Transmitter. (No. 1,280,566; issued to John J. Sherry and John L. DuFrane.)

A clever mechanical arrangement comprising an automatic machine for sending distress signals and dashes, such as on a telegraph or radio circuit, by means of the apparatus called the "earth" or familiar with the code may send distress messages from a ship, etc. The device should prove a fine auxiliary in all ship radio rooms, especially in case of fire, etc., as the transmitter could keep the radio apparatus sending out distress calls with location and name of ship, even though the operator had to abandon the wireless room. There is provided a circular disk with a groove around its periphery, and in this groove there can be placed various telegraphic characters, made of clay and spaced thus the notched slugs corresponding to dots and dashes actuate a cam member, opening and closing electric contacts in the manner apparent.

Electrical Experimentaler.

February, 1919

Dancing Toy. (No. 1,280,307; issued to Harry Bunt.)

This is an interesting electric toy and comprises a jointed doll or other figure suspended at the top in the manner shown. Underneath the figure there is a spring platform, one end of which is provided with an electric contact, and also an electromagnet to attract it. The action is as follows: When the switch is closed, the magnet attracts one end of the spring armature, but immediately the circuit is broken and it flies back. These rapid vibrations of the spring over the magnet, transmit similar impulses to the opposite end of the armature which forms the tread under the figure, and which results in many curious and grotesque stops being evolved for the amusement of the children.

Novel Telephone Receiver. (No. 1,283,304; issued to Thomas Rhodes.)

The receiver as shown is of the monocular type, and the central iron core is secured to a flat base plate. In the improvement here shown, the bell base is formed with radial spires in its marginal portion to provide a series of integrally connected sectors corresponding in number with the series of independent sections which constitute the outer anular pole-piece. This pole-piece comprises a series of radially disposed iron sections. The bobbin of the coil is 70 ohms for telephonic work.

Electromechanical Interupter. (No. 1,283,388; issued to Francois de Cannart d'Hamalle.)

A unique electromechanical interrupter wherein the circuit is made and broken, not by virtue of an electromagnet acting on an armature and pulling it away from a stationary contact screw, but by means of a weighted auxiliary spring placed in a hermetically sealed compartment and acting by means of the weight supported at the top of the contact spring tends to keep on moving when the armature itself is suddenly stopped by striking against the contact point, thus providing a very sudden break, which is highly desirable for operating induction coils.

Electric Lamp Fountain. (No. 1,280,784; issued to Matt Lockenhart.)

An electric lamp fountain operated by the heat radiated from the incandescent lamp placed in a conical chamber in which there is an expansive fluid such as air. The inventor mentions that a 150-watt lamp has worked the apparatus. The liquid sprayed out thru the small capillary tube falls back into a second chamber, thru which the water can reach the inner chamber again thru a check valve. A thermostat may be used to make and break the circuit intermittently when desired. The cover of the fountain may be of glass and colored when preferred for the purpose of transmitting upward thru the fountain spray a portion of the light from the lamp.

Electric Phonograph. (No. 1,281,382; issued to Hans Brockmuller.)

The idea is to provide a simple form of electric motor-driven phonograph with separable record turn-table and tone arm, so that for economical and other reasons it is not necessary to have a large special cabinet about the house. Any cabinet can be quickly converted into a first-class phonograph by the addition of a turn-table and a vertically driven shaft being secured underneath the table. The turn-table has a shaft which passes thru a hole in the top of the table, so as to engage the driving shaft frictionally. The tone arm has a special suction foot which does not require any screws, and the sound emanates around this foot.
Our Amateur Laboratory Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of apparatus unaccompanied by that of the owner. Dark photos preferred to light-toned ones. We pay $1.00 prize each month for the best photo. Address the Editor, "With the Amateurs" Dept.

"Amateur Electrical Laboratory" Contest

THIS MONTH'S $3.00 PRIZE WINNERS—F. L. BROOKS and W. P. CECIL

The accompanying photos are views of our Electro Chemical Laboratory and Radio Station (which is now closed). We have quite a number of electrical apparatus such as Oudin and Tesla coils, motors, spark coils, 12 volt storage battery, Leyden jars, electrolytic interrupter, galvanometer—which was described in the ELECTRICAL EXPERIMENTER several months ago, 50 watt step-down transformer, also 200 watt transformer located behind switch-board and controlled by a five point switch, ammeter and voltmeter also on switch board, arc spot light which will throw a beam of light over a mile, small step-up transformer, condenser and spark gap. Our Chemical "Lab" consists of about 85 chemicals and about 15 pieces of apparatus such as test tubes, Florence flasks, delivery tubes, hydrometer and other apparatus for carrying on experiments on a small scale. Last of all comes our work bench where everything has its beginning. We have a vise, gasoline blow torch, pliers, screw-drivers, twist drills and numerous other accessories. We also have a good supply of binding posts, screws, magnet wire, copper, brass and all such junk as is found in a red-headed bug's "Lab" like my pal's, not saying anything of myself—Floyd L. Brooks and Wm. P. Cecil, Ardmore, Oklahoma.

HONORABLE MENTION (1 Year's Subscription to the "ELECTRICAL EXPERIMENTER") T. C. QUAYLE

My Chemical "Lab" consists of over 150 chemicals and reagents, also apparatus such as pipettes, burettes, retorts, test tubes, thistle tubes, delivery tubes, crucibles, caserole, condensers, a Centigrade-Fahrenheit thermometer, chemists' scales, and many other pieces of laboratory glassware and apparatus, with which I carry on many interesting experiments in quantitative, qualitative and spectrum analysis. I also have gas, a Bunsen burner and a spout for water in the "Lab", and have made a storage battery as described in the 1917 (Nov.) issue, also an arc searchlight, experimental arc furnace, magnetless buzzer, selenium cell (Bidwell type), Wheatstone bridge, electroscope, electrophorus, (sensitive) ohmimeter, electrolytic rectifier and interrupter, Leyden jars, and many other pieces of apparatus described in the ELECTRICAL EXPERIMENTER. I also have an Oudin coil which is operated by an E. I. Co. half kilowatt coil and a rotary spark gap of my own design, also 110 volt and battery motors, hand generator, hot wire ammeter, small storage cell, switches, fuse blocks, Geissler tubes, etc.

My work-shop is complete in tools for both wood and metal working and here is where I made the articles described in the "E. E." I have drills for both wood and metal, braces, chisels, files, saws, wrenches, planes, pickers, levels, two sets of taps and dies, one for small rods, the other for pipes, also an enery wheel and bench lathe, which I designed and built—Thomas C. Quayle, Berkeley, Cal.
Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Offizz for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00!!

When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

HUN U-BOAT UTILIZER

Prize Winner: HUN U-BOAT UTILIZER. Particularly Adapted for Traffic Over Deserts. Take One Gyro Electric Destroyer a la Gernsback, Knock Out All Machinery, Axles, etc., and Mount Plate Glass 16-inches Thick in Framework Covering Both Sides. Make Waterproof and Fill Cruiser with Pure Prohibition Liquid; Also one Hun Submarine. Weight of Submarine Pressing Against Sides, as Shown, Navigates Cruiser at Rate of 25 Knots an Hour with a Fair Zephyr Breeze Nor' by West. Inventor, Jose Matz, 300 Baker St., San Francisco, Cal.

I'SCREAM GENERATOR

I'SCREAM PARLOR GENERATOR. In Order to Save Tremendous Energy Now Going to Waste in All Ice-Cream Parlors, Due to Rotating Seats, My New Patent Provides Extending Shaft to the Rotating Seat, Which Shaft Operates Rotary Air Compressor. This Control Operates Air Tank, Air Motor, Dynamo, etc. The Great Advantage to this Scheme Is That the Device Works Better the More Ice-Cream You Eat Because of the Added Momentum. Separate Patent Application Provides to Charge Customers an Extra Nickel for Allowing Them to Spin Around. Hoover says Economize, Hence no Free Rides. Inventor, Garrett W. Lewis, Yuba City, Cal.
HURLING THE VOICE ONE MILE.

(929) W. J. M. asks:
Q. 1. Is there any practical way of enormously amplifying the human voice so that same can be distinctly heard for a radius of, say, a mile, the atmosphere being comparatively free of other disturbances at the time?

I understand that there are telephone transmitters now made for handling heavy currents of electricity. It occurs to me that possibly the above could be accomplished by using such a transmitter in connection with a mammoth receiver and a suitable horn.

A. 1. One of the leading phonograph companies have developed a very clear and powerful form of comprest air amplifier which we believe might be worked up on a sufficiently large scale to answer your requirements. In this system a low power aural or electrical voice signal is caused to act, by means of a relay or other appropriate device, on an extremely sensitive valve, which permits successive puffs of comprest air from a tank or bellows to pass out thru a large amplifying horn and reproducer. We also believe that the de Forest amplifier might solve your problem, as one model is capable of amplifying 1,000,000 (one million) times. Also their Mr. C. V. Logwood has stated that he believes that your problem of amplifying the human voice so that it could be heard for a radius of one mile can be solved by modern engineering design. He states that by means of microphones suitably connected to a large Osclion bulb that he has actually heard the human voice at a distance of one-half mile in California.

The Alexanderison G. E. Co. magnetic amplifier should be of service to you in this connection. This clever and highly efficient magnetic amplifier was described in detail in the March, 1918 issue of the "Oracle". We believe that these amplifiers are being used on a practical basis to amplify voice currents in the telephone lines.

ARTICLES SCHEDULED FOR MARCH "E. E."

"My Inventions"—No. 2 of a series by Dr. Nikola Tesla. Written exclusively for the Electrical Experi-
menter.

"How Powerful Electric Gyros Stabilize Ocean Ships"—Illustrated with excellent photos by J. W. Hor-
sath.

"Multiplex Telephony and Tele-
graphy and How It is Done," written by a Telephone Engineer.

"Exploring Polar Regions and the North Pole by Airplane."

"Locating Ore Bodies Under-
ground by Electricity—A New Method."

A New Talking Motion Picture Invention.

"How Jimmy Saved the Bank"—A cracker-jack electrical story, by E. W. Russel.

"Experiments in Radio-Activity—Part III."

A Wave-meter and Decimeter De-
sign for Radio Students, Operators and Inspectors. With data on In-
ductances, condensers, etc., by H. Winfield Secor, Assoc., R. E. Prac-
tical Electro-plating, by Joseph Haas.

"Experiments With Ultra-Violet Light, for Amateurs," by J. C. Morris, Jr.

in the April, 1916, issue of the Proceedings of the Institute of Radio Engineers.

Several companies manufacture straight electro-magnetic systems of amplifying the voice, which systems are operated from 110 volt circuits. We can supply names of these concerns on receipt of stamped enve-
lope.

Relative to these systems, the Oracle Editor would say that he has heard the loud talker put out by both of these concerns throw the voice a distance of from 800 to 1,000 feet. The horns used are not over 2 feet long in this system, but the makers utilize special electro-magnetic reproducers which are connected in parallel when two or more are used, and these in turn are con-
nected in series with a special microphone capable of operating on 110 volts D. C. and a bank of incandescent lamps.

ODIN COIL CONNECTION.

(980) Forrest A. Miller, Shelbyville, Kentucky, writes:
Q. 1. Asking several questions about Oudin and Tesla coils.
A. 1. By means of high frequency Tesla or Oudin currents you can charge the body so as to emit sparks and charge other bodies or persons, etc., and you will find the appar-
atus and method of doing this completely described in the book you are se-
curing, viz.: "The Experimental Electricity Course," which contains a special chapter on high frequency currents, with diagrams and full description of the apparatus used.

We can also very highly recommend a book by Transtrom, entitled "Electricity at High Pressures and Frequencies" which our "Book Department" can supply at $2.15 price.

The diagram herewith shows how a spark coil, Leyden jars, spark gap and Oudin type of high frequency coil are properly connected. The ground connec-
tion is optional, but usually intensifies the unpolar discharge for electro-therapeutic requirements.

SIX-INCH SPARK COIL DATA.

(981) Marshall M. Wrenn, Baltimore, Md., asks the Oracle:
Q. 1. For data on six-inch spark induction coil.

(Continued on page 726)
FREE Test Lesson In Draftsmanship

Send for this free lesson which explains the Chicago "Tech" method of teaching Draftsmanship by mail. Positions at big salaries are now waiting for competent men. Even draftsmen of limited training and experience are snapped up and paid good salaries. If you are dissatisfied with your opportunities, learn Draftsmanship. Chicago "Tech" will train you in the most practical way in the shortest time. Mail the coupon today and let us tell you about the Chicago "Tech" method. The free lesson will show you how well equipped you are to follow Draftsmanship. Enroll in the course only if you decide that you can take it up to advantage. No cost, no obligation on you to make this investigation. Send the coupon.

$25 to $100 a Week
Draftsmen always command good salaries. And now when American industries are to be called up on to meet vast foreign and increased domestic demands, the opportunities are greater than ever. This is the time for you to prepare for a better position—a higher salary.

Come to the College or Learn At Home

Hold your present position while training. Our experts will instruct you by mail. Only your spare time is required. You are directly under practical draftsmen and engineers. You are taught exactly the work required in the drafting rooms of big concerns. No time put in on unnecessary studies. This means thorough instruction and early graduation.

Easy Payments
The fees for Chicago "Tech" Courses are very moderate and you can pay on easy terms. And, also, you obtain in a few months what it would take several years to acquire by ordinary methods. You can get an early start. You are soon ready to take a paying position and to quickly get back the cost of your course. Then keep on earning more.

FREE Instruments
Every student of the Chicago "Tech" mail course in Draftsmanship receives this set of instruments, or a cash credit in case he already has a set. These instruments are of the same make and sizes as are used by high salaried experts in drafting rooms of factories, shops, railroads, etc. You use them while learning—then take them right into your practical work.

Auto and Gas Engine Course
All about automobile mechanism—its construction, operation and REPAIR, taught by mail. You take direct under the Chicago "Tech" automobile experts. Spindled opportunities open now. Send coupon and get all the facts.

Learn All This in Sparse Time
Principles of the Automobile. Every part made clear. The working parts of the engine explained. Applications in pleasure and commercial cars, etc., etc.

Gasoline Engines. All about the different types. A complete course in engine construction, operation and repair.

Lubrication and Coolings. Application of power by 4-6-12 cylinder engines. Types of clutches, gears, drives, and transmission.

Carburetors and Fuel Supply Systems. All methods demonstrated. Fuel values. How to test. Gasoline and oil mixtures. Lubrication, care and maintenance, etc., etc.

Send the Coupon—Now

The sooner you are prepared the sooner you will be holding a job that pays a large salary and opens the way to advancement. Many executives, general managers and superintendents began as draftsmen.

CHICAGO TECHNICAL COLLEGE, 245 Chicago "Tech" Bldg., Chicago, Ill.

Without obligation to me, please send me your FREE Test Lesson and other interesting literature covering the subject indicated below Mark X opposite work in which you are especially interested:

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
The primary conductor to be connected across the vibrator should comprise 450 sq. in. if there are less than six wires and interspersed between slightly larger paraffin sheets. If an electrolytic interrupter is used on 110 volts A. C. or D. C. there are no prime requirements.

There should be a hard rubber insulating tube between the primary and secondary coils. The dimensions of this tube should be 2 x 1/4 x 1/16" wall.

The secondary consists of thirty-eight coils, each 1/4th thick, having an outside diameter of 3/4". The spools should be placed between each section six pieces of well-soaked paraffin paper.

An excellent book dealing exclusively on spark coils building can be obtained from our "Book Department" for $3.00.

The title of this book is "Design and Construction of Induction Coils," by Collins. In this book there are sketches for the construction of spark coils such as core dimensions, size of wire, length of primaries, etc.

DATA ON WIRELESS POWER TRANSMISSION.

(98) By Paul V. Page, Detroit, Michigan, writes the "Oracle":

Q. 1. The sketch herewith shows my idea on the wireless transmission of power. Where can I find engineering data on the design of such a system? How can I figure the voltage required to transmit a given kilowattage over a certain distance? etc., etc.

A. 1. We have examined your query, together with diagram showing your ideas for the wireless transmission of power to railway cars, etc.

We regret to say that there is at the present time no engineering data available for solving such problems as outlined, as while Nikola Tesla has successfully lighted lamps and operated motors by the one wire and no-wire wireless system for distances of 60 miles, in the experiments, this branch of advanced alternating current engineering has not been made available in book-text book form as yet.

You would do well to visit your public library and look up Dr. Tesla's book, entitled "Experiments with Currents of High Potential and Frequency".

ELECTRICAL EXPERIMENTER
February, 1919

THE ORACLE.
(Continued from page 724)

A. 1. We give you herewith necessary information for constructing a six-inch jump spark coil.

Primary, 24 ft. No. 13 D. C. C. wire.
Secondary, 7 lbs. No. 36 double silk covered wire (or enameled).
Core, 1/4 x 14" soft iron wire (thoroly annealed).

The primary condenser to be connected across the vibrator should comprise 450 sq. in., if there are six wires and interspersed between slightly larger paraffin sheets.

An electrolytic interrupter is used on 110 volts A. C. or D. C. There are no prime requirements.

There should be a hard rubber insulating tube between the primary and secondary coils. The dimensions of this tube should be 2 x 1/4 x 1/16" wall.

The secondary consists of thirty-eight coils, each 1/4" thick, having an outside diameter of 3/4".

The spools should be placed between each section six pieces of well-soaked paraffin paper.

An excellent book dealing exclusively on spark coils building can be obtained from our "Book Department" for $3.00.

The title of this book is "Design and Construction of Induction Coils," by Collins. In this book there are sketches for the construction of spark coils such as core dimensions, size of wire, length of primaries, etc.

PRACTICAL ARMATURE AND MAGNET WINDING METHODS, by Marsan & Touhey. Leather covers, 252 pages, 128 illustrations, size 4½ x 6½ inches. Price $1.00 in cloth; $1.50 in leather. Published by Frederick J. Drake & Co., Chicago.

This is a handbook for the practical electrician, especially drawn with regard to winding troubles and faults in the windings, armature calculations with wire tables, alternating current windings, etc. The authors give the principles with special illustrations of armature design, armature windings and the mechanical features such as winding firsts of different types of armatures, etc. The section on armature problems gives the necessary information for laying out drum and lap windings, and applies to dynamo pole.

The authors then give a discussion on armature troubles and faults in the windings, armature calculations with wire tables, alternating current windings, etc. One of the most interesting sections is the work on that field magnet winding, and of course this applies to magnet winding of any type. The special formulas and tables given greatly facilitate and simplify the calculation of field and other magnet windings, and it is written in clear language so that any student can grasp the simple arithmetic involved after once reading it. An appendix of useful tables is given at the end of the book which will prove of great value in conjunction with the work treated upon.

An excellent course on flying instruction which is very ably illustrated by comprehensive sketches and diagrams. It covers the essentials of modern sailing and gliding planes and methods of operation of the air in air. This book, with its clear text, practical advice, and the practical help of the pilot, is one that any aviator or flying enthusiast can read with profit, and it will greatly improve his understanding of the heavier and more powerful flying machines into the hands of Flight-Commander of the British Royal Navy and other experts of the United States.

The chapters are subdivided under departmental heads, so that the book forms a very excellent reference work, as well as a well-organized and general reading volume. Flight-Commander McMinnies is the author of many books and covers such points as—"which men make good pilots," "building and flying," a chapter on the subject of applied psychology. As we pass through the elementary stages of both the machine and its component parts, we find the text and drawings so interesting, that it does not tire us at all.

Some very excellent diagrams and drawings are given, showing the various stages of building and how they occur, also how all the fancy tricks are performed in an age of the matter. The sections treating on cross-country flying and determination of distances and altitudes are very important. All the text is clearly written and treated on in a manner following the excellent by the Allied fliers on the Western front.

This volume contains some of the most interesting lectures given by Dr. Steimets, and forms a valuable work which will find a welcome in the library of every engineer, electrical man and student of electrical engineering, as Dr. Steimets is a speaker and writer of articles which are always well considered and pointed. In his typical manner, the lectures are presented, the reader will be surprised at the wide field covered by these lectures. The lectures are divided into two parts, the first part dealing with the important types of lamp and their relevant operational characteristics. The lectures are intended to be a complete and comprehensive guide to any electrical engineer, of all his friends in the field, and of all his friends and colleagues. The lectures are written in a clear and concise manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner, and are written in an excellent and comprehensive manner.
Thousands of skilled Electricians are needed. The demand is becoming more urgent every day. The big Industries are employing every one they can get, causing a great scarcity of trained men, throughout the country. **Big salaries are being paid everywhere.** Right now is your big opportunity. Make up your mind now to prepare for one of these big jobs and then get here as quick as you can for your training.

**Earn $150.00 to $450.00 A Month**

In the Electrical business. Come here where you will be trained in these great $93,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

**The War is Over — Yes!**

but the men “over there” will not be back for months—perhaps years, for their work “over there” isn’t over. And so you, and thousands more must fill up the gap now that the absence of these brave workers has made in the ranks of skilled labor. **Trained Electricians are needed more, perhaps, than any other class of men.**

The sudden ending of the war has caused the big Industries to start up work sooner than any of us expected and in consequence the Manufacturers are Calling for Trained Men, and we are training men as fast as we can to meet these urgent calls. **You are needed, Young Man, now!**

Don’t wait. Don’t put it off. Get in touch with us “Today.” Get ready to join the great “Peace Army” here at home. Your country calls. Again we say, prepare to serve your country! We’ll make a trained electrician of you in three months! Let’s go!

**LEARN DRAFTING**

Skilled Draftsmen are always in demand. Our courses are thorough—short—practical, preparing a man fully to hold a position of responsibility. We have more positions than we can fill. We also have thorough practical courses in Plumbing and Heating and Motion Picture Operating.

**EARN YOUR WAY**

Many students earn a large part of their living expenses by doing a little work in their spare time. Our employment department furnishes these positions without charge.

Famous Scientific Illusions

(Continued from page 694)

The earliest trials were made by Dali- brand in France, but Franklin himself was the first to obtain a spark by using a kite, in June, 1752. When these atmospheric discharges manifest themselves today in our wireless station we feel annoyed and wish that they would stop, but to the man who discovered them they brought tears of joy.

The lightning conductor in its classical form was invented by Benjamin Franklin in 1752 and immediately upon its adoption proved a success to a degree. As usual, however, its virtues were often exaggerated. So, for instance, it was seriously claimed that in the city of Pietermaritz- burg (capital of Natal, South Africa) no lightning strokes occurred after the pointed rods were installed, silhou the storms were as frequent as before. Experience has shown that just the opposite is true. A modern city like New York, presenting innumerable sharp points and projections in good contact with the earth, is struck much more often than equivalent area of land. Statistical records, carefully compiled and examined over a long time, demonstrate that the danger from lightning to property and life has been reduced to a small percentage by the use of lightning conductors, but the damage by fire amounts, nevertheless, to several million dollars annually. It is astonishing that this device, which has been in universal use for more than one century and a half, should be found to involve a gross fallacy in design and construction which renders its usefulness and may even render its employment hazardous under certain conditions.

For explanation of this curious fact I may refer to Fig. 3, in which \( r \) is a metallic sphere of radius \( r \), such as the capacity terminal of a static machine, provided with a sharply pointed pin of length \( h \), as indicated. It is well known that the latter has the property of quickly dissipating the accumulated charge into the air.

To examine this action in the light of present knowledge we may liken electric potential to temperature. Imagine that sphere \( s \) is heated to \( T \) degrees and that the pin or metal bar is a perfect conductor of heat so that its extreme end is at the same tem-
“Here’s an Extra $50, Grace
—I’m making real money now!”

“Yes, I’ve been keeping it a secret until pay day came. I’ve been promoted with an increase of $50 a month. And the first extra money is yours. Just a little reward for urging me to study at home. The boss says my spare time training has made me a valuable man to the firm and there’s more money coming soon. We’re starting up easy street, Grace, thanks to you and the I. C. S.!”

Today more than ever before, money is what counts. The cost of living is mounting month by month. You can’t get along on what you have been making. Somehow, you’ve simply got to increase your earnings.

Fortunately for you hundreds of thousands of other men have proved there is an unfailing way to do it. Train yourself for bigger work, learn to do some one thing well and employers will be glad to pay you real money for your special knowledge.

You can get the training that will prepare you for the position you want in the work you like best, whatever it may be. You can get it without sacrificing a day or a dollar from your present occupation. You can get it at home, in spare time, through the International Correspondence Schools.

It is the business of the I. C. S. to prepare men in just your circumstances for better positions at better pay. They have been doing it for 27 years. They have helped two million other men and women. They are training over 100,000 now. Every day many students write to tell of advancements and increased salaries already won.

You have the same chance they had. What are you going to do with it? Can you afford to let a single priceless hour pass without at least finding out what the I. C. S. can do for you? Here is all we ask—without cost, without obligating yourself in any way, simply mark and mail this coupon.

International Correspondence Schools
BOX 6173, SCRANTON, PA.

Explain, without obligating me, how I can qualify for the position, or in the outline, before which I mark an X.

ELECTRICAL EXPERIMENTER

FAMOUS SCIENTIFIC ILLUSIONS.
(Continued from page 728)

\[ \frac{nq}{(r+q)} = \frac{q}{r} \]

Thus the difference of potential between the point of the pin and the medium around the same

The positive charge of the cloud induces in the earth an equivalent opposite charge, the density at the surface of the latter diminishing with the cube of the distance from the state center of the earth. A discharge is then formed at the point of the rod and the action Franklin anticipated takes place. In addition, the air is ionized and rendered conducting and, eventually, a bolt may hit the building or some other object in the vicinity. The virtue of the pointed end is to allow the charge, which was uppermost in Franklin's mind, is, however, infinitesimal. Careful measurements show that it would take many years before the electricity stored in a single cloud of moderate size would be drawn off or neutralized through such a lightning conductor. The grounded rod has the quality of rendering harmless most of the strokes it receives, therefore occasionally the charge is diverted with damaging results. But what is very important to note, it invites danger and hazard on account of the fallacy involved in its design. The sharp point which was thought advantageous and indispensable to its operation, is really a defect detracting considerably from the practical value of the device. I have produced a much improved form of lightning protector charging it by employment of a terminal of considerable area and large radius of curvature which makes impossibly uniform density of the charge and neutralization of the air.* These protectors act as quasi-repellents and so far have never been struck tho exposed a long time. Their safety is experimentally demonstrated to greatly exceed that invented by Franklin. By their use property worth millions of dollars which is now annually lost, can be saved.

III. The Singular Misconception of the Wireless.

To the popular mind this sensational advance conveys the impression of a single invention but in reality it is an art, the successful practice of which involves the employment of a great many discoveries and improvements. I viewed it as such when I undertook to solve wireless problems and it is due to this fact that my insight into its underlying principles was clear from their very inception.

In the course of development of my induction motors it became desirable to operate them at high speeds and for this purpose I constructed alternators of relatively

*Refer to the October, 1918, issue of this journal wherein Dr. Tesla's novel use of non-pointed lightning rod was fully described and illustrated.

ELECTRICITY

Taught By A Practical Man
and in Your Home!

IT IS UP TO YOU

I am teaching electricity and drafting to many men, women, and women, and wish to interest you sufficiently so you will send for my catalog which tells the whole story, as it is too much to tell here. It is up to you whether you look into the proposition, but if you are earnest in your desire to get into the electrical industry, or to become more proficient in this line, you will send for the catalog and you will not regret the time you give in doing so.

THE PURPOSE OF THE COURSE OF STUDY

I have been designing courses in electrical instruction and teaching electricity, of and on during the past 17 years, and during that time I have had an unusual opportunity to make a special study of the teaching business, from the standpoint of a practical man. This course of my own is designed with that view of teaching those who do not have a lot of time and money to devote to study work, and give the student the knowledge of the subject which he can build upon, and which will add to the everyday work of electrical experience, and from which conditions I say particular stress on. This part of the instruction is for the course particularly attractive and valuable to those already engaged in some electrical work.

Apparatus, Instruments, Material, Etc.

Equipment, instruments, materials, etc., as detailed in the catalog, are included in the course and are a part of the regular instruction for which there is no extra charge as it is covered by the regular monthly payments.

FILL OUT COUPON FOR ONE OF MY CATALOGS WHICH GIVES FULL INFORMATION.

BURGESS ELECTRICAL SCHOOL
745 E. 42d Street
Chicago, Ill.

To Practical Men and Electrical Students:

(See review of this book by Editor in December issue of your Electrical Experimenter, page 568)

I have prepared a pocket-size note book especially for the practical man and those who are taking up the study of electricity. It contains drawings and diagrams of electrical machinery and connections, over two hundred formulas for calculations, and problems worked out showing how the formulas are used. This data is taken from my personal note book, which was made while on different kinds of work, and I am sure it will be found of value to anyone engaged in the electrical business.

The drawings of connections for electrical apparatus include Motor Starters and Starting Boxes, Overload and Underload Release Boxes, Reversing Types Elevator Controllers, Tank Controllers, Starters for Printing Press Motors, Automatic Controllers, Variable Field Type, Controllers for Mine Locomotives, Street Car Controllers, Connections for reversing Switches, Motor and Dynamo Rules and Rules for Speed Regulation. Also, Connections for Induction Motors and Starters, Delta and Star Connections and Connections for Auto Transformers, and Transformers for Lighting and Power Purposes. The drawings also show all kinds of lighting circuits, including special controls where Three and Four Way Switches are used.

The work on Calculations consist of Simple Electrical Mathematics, Electrical Units, Electrical Connections, Calculating Unknown Resistances, Calculation of Current in Branches of Parallel Circuits, How to Figure Weight of Wire, Wire Gauge Rules, Ohm's Law, Watt's Law, Information regarding Wire used for Electrical Purposes, Wire Calculations, Wiring Calculations, Illumination Calculations, Shunt Instruments and How to Calculate Resistance of Shunts, Power Calculations, Efficiency Calculations, Measuring Unknown Resistances, Dynamo and Dynamo Troubles, Motors and Motor Troubles, and Calculating Size of Pulleys.

Also Alternating Current Calculations in finding Impedance, Reactance, Inductance, Frequency, Alternations, Speed of Alternators and Motors, Number of Poles in Alternators or Motors, Conductance, Susceptance, Admittance, Amplitude, Angle of Lag and Power Factor, and formulas for use with Line Transformers.

The book called the "Burgess Blue Book" is published and sold by the Burgess Engineering Company for one dollar ($1.00) per copy, postpaid. If you wish one of the books, send me your order with a dollar bill, check or money order. I know the value of the book and can guarantee its satisfaction to you by returning your money if you decide not to keep it after having had it for five days.

Wireless Stations Will Shortly Re-open

Date, only, uncertain

Heed Our Advice

ORDER NOW

As a matter of law Congress loses all control over wireless receiving stations and transmitting stations with a range within the borders of the state where licensed as soon as a law is declared. The Radio Institute, however, has already asked our cooperation in printing in the next edition of our catalog the necessity of securing licenses for transmitting acts with a range over the borders of the state. No wireless manufacturer wants the stations to open today, but he cannot take care of the business. Order now and be prepared.

Wireless Stations Will Shortly Re-open

No. 11 is our latest catalog. No new price list.

Please do not write for catalog if you have No. 11. Paper costs three times as much as formerly. Let the wireless without a catalog secure one. Write for prices in advance. Just now we have no price list, because the changes have been so frequent. Will advise through this magazine when revised price list is ready, which will be as quickly as possible.

Send 8c in coin or stamps today for our big 400 page No. 11 Electrical and Wireless Catalog. Any wireless amateur will tell you it is the one catalog to have. You need no others. Our catalog contains most everything in wireless worth while, and is a guarantee that the goods are dependable.

FAMOUS SCIENTIFIC ILLUSIONS

(Continued from page 730)

high frequencies. The striking behavior of the currents soon captured my attention and in 1889 I published a systotic investigation of their properties and the possibilities of practical application. The first gratifying result of my efforts in this direction was the transmission of electrical energy thru one wire without return, of which I gave demonstrations in my lectures and addresses before several scientific bodies here and abroad in 1891 and 1892. During that period, while working with my oscillation transformers and dynamos of frequencies up to 600,000 per second, the idea gradually took hold of me that the earth might be used in place of the wire, thus dispensing with artificial conductors altogether. The immensity of the globe seemed an unsurmountable obstacle but after a prolonged study of the subject I became satisfied that the undertaking was rational, and in my lectures before the Franklin Institute and National Electric Light Association early in 1893 I gave the outline of the system I had conceived. In the last paragraph of Chichakly's World's Fair, I had the good fortune of meeting Prof. Helmholtz to whom I explained my plan, illustrating it with experiments. On that occasion I asked the celebrity physicist for an expression of opinion on the feasibility of the scheme. He stated unhesitatingly that it was practicable, provided I could perfect the device of putting it into effect but this, he anticipated, would be extremely difficult to accomplish.

I assumed the work very much encouraged and from that date to 1896 advanced slowly but steadily, making a number of improvements. The chief of which was my system of "concentration and dispersal" as a method of regulation, now universally adopted. In the summer of 1897 Lord Kelvin happened to pass thru New York and honored me by visiting my experiments where I entertained him with demonstrations in support of my wireless theory. He was very much interested and enthusiastic but, nevertheless, condemned my project in emphatic terms, qualifying it as something impossible, "an illusion and a snare." I had expected his approval, but I was not surprised. But the next day he returned and gave me a better opportunity for explanation of the advances I had made and the true nature of my system. In my system the process is one of true conduction which, theoretically, can be effected at the greatest distance without appreciable loss. I can never forget the change of attitude that came over the famous philosopher the moment he freed himself from that erroneous impression. The skeptic who would not believe was suddenly transformed into the warmest supporterers. He parted from me not only thoroughly convinced of the scientific soundness of the idea but strongly exhorting an effort in its success. In my exposition to him I resorted to the following mechanical analogues of my own and the Hertz wave system.

Imagine the earth to be a bag of rubber filled with water, a small quantity of which is periodically forced in and out of the bag in the shape of a wave. As the waves are transmitted, they are reflected from the sides. If the strokes of the latter are affected in intervals of more than one hour and forty-eight minutes, sufficient for the transmission of the impulses thru the whole mass, the entire bag will expand and contract and corresponding movements will be imparted to the medium. Pistons with the same intensity, irrespective of distance. By working the pump faster, shorter waves will be produced which, on reaching the opposite end of the bag may be reflected and give rise to stationary nodes and loops, but, in any case, the fluid being incompressible, its inclosure perfectly elastic, and the frequency of oscillations not very high, the energy will be economically transmitted and very little power consumed. It is longer than not making for the receivers. This is a crude but correct representation of my wireless system in which, however, I resort to various refinements. Thus, for instance, when the circuit of a resonant system of great inertia, enormously magnifying the force of the impulses. The receiving devices are similarly conditioned and in this manner the amount of energy collected in them vastly increased.

The Hertz wave system is in many respects the very opposite of this. To explain it by analogy, the piston of the pump is assumed to vibrate to and fro at a terrific rate and the greatest quantity of fluid passes in and out of the cylinder is reduced to a small hole. There is scarcely any movement of the fluid and almost the whole work performed results in the production of radiant heat, of which an infinitesimal part is recovered in a remote receiving. However incredible, it is true that
the minds of some of the ablest experts have been from the beginning, and still are, obest by this monstrous idea, and so it continues carelessly, for which I founded the foundation in 1893, has been re-
tarded in its development for twenty years. This is the reason why the "statics" have produced a great deal of interest why the "mechanics" are of little value and why the Gov-
ernment has been compelled to interfere.

We are living on a planet of well-nigh in-
finite extent, surrounded by a non-conducting layer of insulating air above which is a
rarefied and conducting atmosphere (Fig. 5). This is providential, for if all the air were to be completely replaced by insulation, elec-
trical energy thru the natural media would be impossible. My early experiments have shown that if high frequency waves are sent across a considerable distance, without being ab-
sorbed. The theory has been seriously ad-
vanced that these radiations pass around the earth with infinite"efficiency," but it is clear that the show the absurdity of this suggestion reference is made to Fig. 7 in which this process is dia-
grammatically indicated. Assuming that there is no refraction, the rays, as shown on the right, would travel along the sides of a polygon drawn around the solid, and the direction of transmission of the waves as a boundary in which case the length of the side would be about 400 miles. As one-
half the circumference of the earth is ap-
proximately 25,000 miles, there are roughly, thirty deviations. The efficiency of such a reflector cannot be more than 25 per cent, so that if none of the energy of the waves are absorbed in one deviation, the part recovered would be measured by the fraction (3/4)^30. Let the transmitter radiate
Hertz waves at the rate of 1000 kilo-
watts. Then about one hundred and fifteen billionth part of one watt is all that would be collected in a perfect receiver. In truth, that is as good as nothing. It is inconmis-
urable as shown on the left of the figure, and owing to this and other reasons, on which it is unnecessary to dwell, the amount recovered is nothing.

Consider now the process taking place in the transmission by the instrumentality of the wireless telephone. The object of this purpose attention is called to Fig. 8, which gives an idea of the mode of propagation of the current waves and is largely self-
explanatory. The drawing represents a
solar eclipse with the shadow of the moon just touching the surface of the earth at a point where the transmitter is located. As the shadow falls over the earth's surface, first with infinite, and then gradually diminishing velocity until the sun's rays will again will attain its true speed in space. From on it there will proceed with increasing velocity, reaching infinite value at the op-
posite side of the earth. It has already be
en stated that this is merely an illustration and not an accurate representation in the astrono-
mical sense.

The diagram will be readily understood by reference to Fig. 9, in which a transmitting circuit is shown connected to earth and to the transmitter being in action, two effects are produced, viz: electrical waves pass thru the air, and a current traverses the earth. The former wave travels thru the light and the latter has nowhere to go. It is the latter which is uncovered in the circuit. The latter proceeds with the speed varying as the cosecant of the angle which a radius drawn from any point under consideration forms with the central axis, and becomes greater as the earth is approached.

In conclusion I wish to add that the work that I have been doing for years, in the design of the telephone, but have not been permitted to make public in any form, has been of the greatest value to me. I have always been be
lieved that the telephone is one of the greatest inventions of all time, and I am convinced that it will ultimately become the greatest.
ELECTRICAL QUADRANT NOTE

BODINE Motors

We have 1000 NEW WASHING MACHINE MOTORS. These are of standard manufacture and carry the regular factory guarantee. Shipped in original boxes. Complete as cut.

Bought from Bankruptcy Stock

Suitable for operating Coffee Grinders, Cream Separators, Bottle Washers, Air Compressors, Small Lathes, etc.

Mail $5.00 cash or Money Order. We will COD, subject to full examination.

MONEY BACK GUARANTEED

MANUFACTURERS' DISTRIBUTORS

GHAS. H. JOHNSTON - WEST END - Pittsburgh, Pa.

Wireless Taught By Mail

Merchant Marine Needs THOUSANDS of Operators

Men also needed for big Land Wireless Stations - Air Mail Service - Telegraph companies. Salaries up to $260 a month. Excellent opportunities to win promotion to Radio Engineer - Inspector or Draftsmen. Chance to travel the world over or locate at Land Station in America.

Complete Course by Mail in Ten Weeks

Our students actually pass the commercial examination in Ten Weeks or less. Start studying NOW in spare time at home. We send you Complete set of Practice Examinations and sending messages, with full instruction. We help you secure position in any branch of Commercial or Government Radio Service. Write TODAY for Free Particulars. A prospect will do.

SKINDERVKEN TRANSMITTER BUTTON

Fig. 1

The SKINDERVKEN TRANSMITTER BUTTON can be placed in any position and it will talk loudly and distinctly and is at the same time extraordinarily sensitive. It was primarily designed to replace the old damaged or burnt out transmitter. Simply unscrew and remove the transmitter from inside the wires, unscrew and remove the bridge and the old electrode. There remains only the diaphragm. These wires are then connected with the Skinderviken button, the latter screwed to the diaphragm, and after screwing the old transmitter housing together again, the telephone is ready for work.

ELECTRICAL EXPERIMENTER readers will be particularly interested in all the different experiments that can be performed with the Skinderviken Button. Fig. 1 shows the Skinderviken button attached to the back of an ingot steel watch case. When speaking towards the inside of the case, it will be found that the button transmits with the axis of symmetry of the waves. At the origin the speed is infinite but gradually diminishes until a quadrature is traversed, when the velocity is that of light. From there on it again increases, becoming infinite at the antipode. Theoretically the energy of this current is recoverable in its entirety, in properly attuned receivers.

Some experts, whom I have credited with better knowledge, have for years contended that my proposals to transmit power without wires are sheer nonsense but I note that they are growing more cautious every day. The latest objections to my method is found in the cheapness of gasoline. These men labor under the impression that the energy flows in all directions and that, therefore, only a minute amount can be recovered in any individual receiver. But this is far from being so. The power is conveyed in only one direction, from the transmitter to the receiver, and none of it is lost elsewhere. It is perfectly practicable to recover at any point of the globe energy enough for driving an airplane, or a pleasure boat or for lighting a dwelling. I am especially sanguine in regard to the lighting of isolated places and believe that a more economical and convenient method can hardly be devised. The future will show whether my foresight is as accurate now as it has proved heretofore.

SHIP RADIO OPERATORS ASK INCREASED WAGES.

Increased wages and the fixing of a standard wage scale for radio operators on vessels operating under Government direction was asked of the Shipping Board recently by a delegation representing the Marconi Radio Telegraphers' Association. The radio operators included in the request made of the Board are those on vessels operating in transatlantic and Gulf waters. Assurances were given the radio representatives by Board officials that their request would be taken under advisement for immediate consideration.

ALEXANDER WIRELESS BILL, AMENDED.

"Good Night." It would, of course, hold out all the sending stations which I have mentioned other than private ones, with one stroke. If we must have a time limit, let it be stated in the law so there will not be any "Ifs" and "hows" at all such clause as this would tend to create jealousy and friction between amateurs and Government officials. We believe such a clause is unnecessary and only at best reflects on Government apparatus and therefore inefficient Government radio operators.

No objection to this, although every amateur operator before the war was only too proud to display his Government license, once he had gone to the trouble to get one.

"Fifteenth. The owner of any private or amateur station must, within six months, after the date of the regulations of the Government stations and failure, to do so shall be liable by a fine not exceeding $100, such rules and regulations to be furnished by the Government at a nominal cost."

No objection to this.

RADIO AMATEURS DISCUSS OFFICIALLY.

During the hearings of the Alexander Bill before the committee on the Merchant Marine and Fisheries on December 12, 1918, many interesting points were brought out.

Lieut. Cooper, Jr., U. S. N. R. F., had been intrusted with drafting the amateur amendment, printed elsewhere in this issue. He called him self an "amateur naval officer," undertook the thankless job of drafting an amendment which would satisfy both the Navy and amateurs. As Lieutenant Cooper, let us state that he tried hard to be fair to both interests. But it is our opinion that neither Navy Department nor Amateurs are satisfied with the compromising amendment.

Lieutenant Cooper's statement before the committee.

Statement of Lieut. J. C. Cooper, United States Naval Reserve Force.

Lieut. Cooper: Gentlemen, I am an ex-amateur radio operator and "amateur naval officer," as I am told. I will take up the practice of my profession again. As many amateurs, when questioned, tell us offhand to do what I could for the service, I have had some duties in connection with radio work which have given me an opportunity to be able to see the point of view of the Navy and the point of view of the amateur as well as the same point of view.

Several days ago there was a meeting called in Capt. Todd's office—without knowing how many men who would be possible amateurs who happened to be on duty in the naval service in Washington. There were about 25 or 40 men present.

The question of the operation of amateur stations after the war was very liberally discussed, and a memorandum was prepared and sent to each of the men and the men in the naval service in Washington. We had been amateurs that we could locate, with the request that the questions be answered and sent back as soon as possible, with an idea of drafting an amendment to the present law which would, as far as possible, meet the combined view of themselves as previous amateurs, knowing amateur operations and knowing what the amateur desires do is a question so long as we have been amateurs.

I have the unfortunate responsibility of having to say the final word on collating those opinions and putting them into the form of an amendment. There is no body of men, I believe, who are more closely associated with everyone else in this country than these amateur radio operators. I am convinced from now on, as these hearings are going to be printed, my name is going to be raised in this connection among the amateurs to some as guilty of high treason, to others as one of the noblest services that a man can perform, and a credit if this amendment goes into law. I do not expect to be able to agree with it all, as I am the individual judge, however, of a certain number of questions that have been seen to the Navy point of view and the amateur point of view, and I, myself, believe that the the Government, and it is offered as an amendment to the bill.

The present law states that the amateur who does not hold a special license is authorized within 3 miles of a Government station to use a transformer input of one-half kilowatt, elsewhere 1 kilowatt.

Try This Wonderful New VIOLET-RAY Machine—10 Days Free!

NOW in your own home you can have wonderful Violet-Ray treatments exactly as are given by eminent physicians and beauty specialists throughout the country. Now you can rid yourself of headaches, catarrh, constipation, eczema, insomnia, lumbago, nervousness. Relieve your pain from neuritis, rheumatism, and other disturbances. Multiply your bodily health, vitalize your nerves, double or treble your energy by using Violet-Rays. Sleep better, increase your strength, and improve your appetite and digestion. Soothe your nerves, reduce or increase your flesh. Tone and strengthen the entire system. Beautify your complexion! All with Violet Rays!

Not a Vibrator

The wonderful Violetta is not a Vibrator. It is not a machine that contracts the muscles—it does not shock, it does not pound the muscles—it is absolutely painless. Violet-Rays administered by the Violetta are wonderful even for infants! Relieve pain and suffering in every part of the body. Simple tests prove that Violet-Rays pass completely through every part of the body, stimulating everything and organ. It is electricity in its highest remedial form.

Treat Yourself at Home

Here is a partial list of ailments treated successfully, with the Violetta, Violet-Ray Machine.

Asthma  Earache  Obesity
Barber's Itch  Exema  Pain  Skin
Boils  Eye Disease  Paralysis  Sore Throat
Blackheads  Falling Hair  Piles
Bronchitis  Hay Fever  Pneumonia
Catarrh  Headache  Pyorrhea
Chilblains  Gout  Rheumatism
Cold  Insomnia  Simple
Corn  Lumbago  Vaccines
Constipation  Nervousness  Venereal
Dandruff  Neuritis  Whooping Cough
Deafness

Write today without fail. Mail coupon or just a post card. Let us send you our 32-page beautifully illustrated free book, describing the Violetta in detail. Read the amazing phenomena produced by Violet-Ray High frequency current. Why it produces stimulation and sedation. How to give spinal treatments with the Violetta, how to treat various ailments, including nervous troubles, rheumatism, obesity, hayfever, skin troubles, facial treatments. Note low price direct to you from our own laboratories. Note the amazingly superior construction of the Violetta in every detail. Mail coupon or postal right now before you turn this page. Violet-Rays will double your energy, will increase your life, will remove your pains and aches. Address

BLEADON-DUN CO., Dept. 2-B, 11-17 So. Desplaines St., Chicago, Ill.
K. I. Shorthand hastened his promotion from stenographer to electrical experimenter. His speed depends upon it more than ever.

You Need K. I. Shorthand Whenever Your Calling

The wonderful thing about K. I. Shorthand is the way it helps people in all walks of life. Engineers, chemists, contractors, clerks, mechanics, professional men and women. And farmers have learned K. I. Shorthand and are enthusiastic in its praise. At last you can learn shorthand so quickly and so inexpensively that it is worth your while. This new, amazingly simple stenography will enable you to put down business rapidly as spoken, take messages verbatim, record board-meeting facts, jot down business-getting ideas, and be ready to help you every time anything important must be written down fully and instantly. You do not have to study months to do this. Just five evenings at home is all that is necessary. Greater success comes quickly with practice. Learn K. I. Shorthand because it will be the biggest time investment of your life.

You Can Learn in 5 evenings

K. I. Shorthand is the ideal system for stenographers or secretaries. Even though you may not know the first thing about shorthand, it is not a bit remarkable for anyone to learn all the lessons in the system that quickly. Why put in months of grinding study at some difficult old-fashioned system? Save time! Save money! Learn K. I. Shorthand, the new easy as A-B-C method of speed writing.

The cost of the course is lower than it has ever been possible to execute; new graphic education. Everyone can afford it. K. I. Shorthand is used in government services and courts as well as public corporations and private businesses. Preferred by highly technical men because of its remarkable accuracy and legibility. Simplified K. I. Shorthand dispenses with all special positions, light and heavy shading and other confusing and speed-reducing rules of old systems. You will be delighted.

Try 2 Lessons FREE

You learn K. I. Shorthand in your own home by mail tuition course. The lessons are fascinating, enjoyable, and practical. Send for two free lessons and complete information—without obligation. Begin our success lessons are written to continue the entire course of this month's approval.

Here is a complete course—not merely a sample—of 12 lessons a month. In fifteen months there is no system to compare with Shorthand Shorthand for ease and rapidity—and to course giving correspondence instruction incomparable at anything like our price. We give you a positive guarantee that you can learn or no cost to you. King Institute is incorporated in New York State $100,000.00 subscribed capital. Mail the coupon or write a letter asking for free lessons and complete information. Be sure to mention "Electrical Experimentalist."

7 Electrical Money Makers Each & a Day!

It's Only a Step to the Big Jobs From Where You Are!

There is a big job waiting for you in the electrical profession. All you need is special training on advanced points which big men must know. And here is all this special knowledge which will enable you to master every electrical problem. This great 7-volume Cyclopaedia of Applied Electricity bridges the gap between your present job and the $5,000 a year job.

50 Years of Electrical Experience

Now at Your Finger Tips

Here in convenient form you will find everything from wiring a bell to the newest wireless discoveries. Tells all about elements of electricity—electrical measurements—underwriter's requirements—theory, calculation, designs and construction of direct current generators and motors—types of generators and motors—management of electrical machinery—electric lighting—alternating current machinery—power transmission—electrical railways—power stations—switchboards and switchgear—applied electro-chemistry—electric elevators—electric welding and heating—wire and wireless telegraphy.

Help You Fill These Jobs

Electrical Engineers, Subscribers, Operators, Switchboard Operators and Managers, all are wanted by light and power companies everywhere. The demand for trained and experienced Electrical Engineers is greater than ever before. The demand for trained and experienced Electrical Engineers is greater than ever before.

Half Price—Easy Terms in ADVANCE

Regular price $15.00 per volume. Special price less than $3.00 per volume. Easy terms only $2.99 a month—less than 1 cent a day per volume. Entire set shipped for free examination—no money to send. Send no money. Just mail the coupon above.

MAIL COUPON NOW

With each set we include a $12.00 Consulting Membership in the American Technical Society, a $12.00 value, at a saving of $12.00. Mail coupon today without money.

ELECTRICAL EXPERIMENTER

February, 1919

Mr. Saunders: I want to ask you a few questions about the amateur business. Have you ever looked over the bill that is under consideration by the committee? Lieut. Cooper: I have read it, sir.

Mr. Saunders: Aside from your amendment you have been discussing, there is no provision in the bill whatever relating to amateurs, is there? Lieut. Cooper: I understand, sir, it was the intention of the department to license amateur operators.

Mr. Saunders: Under the bill that has been introduced there is no provision for the amateur? Lieut. Cooper: No, sir.

Mr. Saunders: Is there under any other name? Lieut. Cooper: I think, sir, there has been no reason why amateur stations should not have been licensed under some section of the "experimental stations."

Mr. Saunders: Suppose it is just an individual, I understand, sir. I understand, sir, a great many of these people who are amateurs took up this thing before the war and young men went up and took up the business themselves.

Lieut. Cooper: I did so myself.

Mr. Saunders: That would not be called a station, would it? Lieut. Cooper: Oh, yes, sir.

Mr. Saunders: Do you think, under the language "experimental stations," that any little individual amateur operator in the wilds of the name, I will say, who has been working on the thing himself, as an intellectual improvement, could be described as an "experimental station."

Lieut. Cooper: I think so. But I say it is a most point in view of the amendment.

Mr. Saunders: I do not see how that could be done with respect to the provision as to who is to be licensed as an amateur. Under that, necessarily there any many more amateurs, he must have had the opportunity to take some preliminary training, at some station.

Lieut. Cooper: Very frankly I think that very few amateurs ever went to a training school.

Mr. Saunders: You mean to say there is no possible classification by certain capacities by your amendment; they have got to have a certain facility.

Lieut. Cooper: The amateur can learn that by putting the buzzer. All amateurs do the same thing, all operators.

Mr. Saunders: Can he experiment enough with the wireless apparatus to acquire that facility without having a trainer?

Lieut. Cooper: May I suggest, sir, that the process would be something like this: That by listening in call—call—call, and you will note that no license is required for receiving—a man can become accustomed to using the receiving apparatus, and he can become accustomed to sending with a key to the buzzer, which is not a radio operator, and he can be taught to send up to any speed he can maintain.

Mr. Saunders: He can teach himself, in other words, can he?

Lieut. Cooper: Teach himself, or be taught by other amateurs.

Mr. Saunders: He can pick that up by his own efforts, and by his own ingenuity and application as a home, he can acquire the facility which you have imposed upon him before he can receive a license.

Lieut. Cooper: I think any of the amateurs here will be able to teach you.

Mr. Saunders: With respect to this amateur, after he has attained that speed, and when he is given the license that you say that your provisions would be controlled by the terms of his license.

Lieut. Cooper: They are at present, under the present provisions.

Mr. Saunders: Do you contemplate any difficulty in that connection if he operates in connection to the terms of his license, with the commercial operation of the Government system, or any other commercial system?

Lieut. Cooper: The limitation of wave lengths, sir, and the limitation to power in accordance with the law of 1913, as amended by this amendment, are designed to prevent the amateur from causing interference with commercial stations.

Mr. Saunders: But you can see no danger of interference with the wireless system in the hands of an experimental operator?

Lieut. Cooper: It was my view, sir, in drafting the amendment as it is, that these limitations on power and wave lengths would prevent such interference.

Mr. Saunders: So that in considering the general problem with respect to the necessity of having the Government business unimpeded by this control, and control, we can eliminate any factor of danger from experimental operators.

Lieut. Cooper: I think so, sir, with the exception of the fact that some of these experimental stations must be had in the future if the amateur is to maintain the dignified position in the radio world as he should.

Mr. Saunders: That is by regulation for me.

Mr. Saunders: As I know, I have eliminated the amateur. I am going to try to substitute a factor in this favoring this policy, because they will operate in a field outside of the field that has been under the control.

Lieut. Cooper: That is the idea of the amendment.

There is one coming factor in radio work which may adversely affect amateur operating which should be looked forward to at the present time. The fleet—and this is not disclosing military secrets—it is used for interference purposes; very short wave length, shorter than the one hundred fifty meters mentioned here as the minimum length that an amateur should use. Aircraft are also using various wave lengths, some of which are almost

(Continued on page 742)
What Drafting Means to the World—and You

Drafting is the Backbone of All Industry

of all construction. The world—its homes, skyscrapers, factories, ships, railroads, and commercial and industrial machinery are all monuments to the draftsman's skill. As a profession—as an avenue for advancement in every known form of engineering—drafting has no equal.

Aim as high as you like and you can reach your mark in this greatest of all professions. Just as the reconstruction of Europe will first have to be planned on the drafting table, so has the world been built—so will the world continue to be built. That is why there is no limit to your success as a draftsman.

Make Drafting Your Profession

The American School Home Study Course will enable you to master this great, interesting and congenial profession without in any way interfering with your present work. Just give us a part of your spare time and we'll do the rest. Our lessons are simplified, well illustrated, easily understood—and we coach you carefully from first lesson to the last.

Draftsmen in Big Demand

Think for a minute of the colossal reconstruction plans of the United States—to say nothing of Europe—and you will get an idea of the busy years ahead for draftsmen in all branches. But there is ALWAYS a big demand for draftsmen—BECAUSE they are the fundamental factors in world's progress.

Don't hesitate. Don't think you can't master our lessons by Home Study until you TRY. So sure are we that you can do as well as any of our thousands of students, we Guarantee Satisfaction or refund your money in full. That's how confident we are in our methods. Have you as much confidence in yourself? If so, check and mail the Coupon for FREE Bulletin.

You benefit by mentioning the “Electrical Experiment” when writing to advertisers.
We present herewith to our friends our new E. I. Co. Chemical Laboratory which contains real chemicals and apparata to perform real chemical experiments. This outfit is not a toy, put up merely to amuse, but a practical laboratory set, with all the chemicals, apparata and reagents necessary to perform real work and to teach the beginner all the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

44 Chemicals
17 Apparata
1 Instruction Book with 100 Experiments

PRICE $5.00

PATENT ADVICE

In this Department we publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Regular inquiries addressed to "Patent Advice" cannot be guaranteed a charge. Such inquiries are published here for the benefit of all future readers. If the idea is thought to be of importance, we make it a rule not to delve all details, in order to protect the idea as far as is possible to do so.

Readers are cordially invited to use the blank form "Evidence of Concepcion" to submit all ideas to us. A sample form together with printed instructions will show just how to fill up your evidence and establish your rights before filing application for patent. As registered patent attorneys we represent hundreds of inventors all over the U. S. and Canada in the advancement of inventions. Our schedule of fees will be found reasonable. The form "Evidence of Concepcion," sample, instructions relating to obtaining of patent and schedule of fees are sent upon request. Ask for a—post card will do.

tubes where a displacement of the liquid will take place gradually, we believe that the device will function with a greater degree of success.

Automatic Air Hose Coupling.

(201) James Wilson, N. Y., submits a drawing of an automatic air hose coupling with drawing, and wishes to have our opinion whether it is patentable and if it would be of any value if a patent could be obtained.

A. It is impossible to figure out on paper whether the hose would work satisfactorily. Indeed, we are not even sure the device is at all new. We would advise our correspondent to have someone search made for him. The assistance of the patent attorneys can ascertain what has been done previously in this art.

Electric Heater.

(303) Gottlieb Samuel Leventhal, Elmira, N. Y., submits a drawing on an electrical idea for heating water. It appears to be of the usual type; whereby it can be attached to any faucet, the water started and the current turned off. As the water runs thru this device and over the heat, the water is heated.

A. There is nothing fundamentally new to the device submitted, nor any regulation or device that our correspondent has given it, which is in the shape of a round ball. Outside of this, there is nothing new here that are quite certain that no patent could be obtained.

Mechanical Brake.

(304) Emilio Man, Havana, C. A., writes as follows: I am enclosing blueprint and description of a contrivance to apply brakes on railroad cars with the idea of publishing it with your advice on the idea in your Patent Advice column. Will you kindly tell me whether the possibilities of this invention?

A. This is a very simple contrivance, and without seeing a model we think it is almost impossible for anyone to give an intelligent opinion. A brake of this kind looks all right on paper, but it is difficult to predict in advance if it will work out in practice. We therefore advise you that before applying for patent on this apparatus that a model should be tried.

BOY BURNED WHEN WET KITE STRING TOUCHES WIRES.

While Wm. Oliver of Port Stanley was amusing himself recently flying his kite he was severely burnt on both hands, when the flying string came in contact with the high voltage wires of a local railway. While flying his kite a strong wind sent it to the ground, and the wire, which was in a relaxed condition, came in contact with this power wire, as it fell over it. The victim got the full benefit of the voltage. This was much too strong for the string as it burnt. Two of his fingers which William is very thankful as it saved his life.

The only other small boy there ran away when he saw what had happened so he was alone when all happened. The burnt hands healed up all right, but Master Oliver, for one, will keep clear of all overhead electric wires hereafter, for he goes kite flying.

It is remarkable that he was not killed outright, the high resistance of the kite string probably being the factor that saved his life.

RADIO AMATEURS DISCUSS OFFICIAL.

(Continued from page 738)

down to 250 meters. There may be trouble in the future, as between aircraft operating over long distances, and working with their receiving or transmitting apparatus, and as the weather is a possibility of the future that I will call the attention of the committee, which this thing may come up here at another time under some future law, and I simply want to warn the com-

mittee that this is a new field that we know nothing about. Aircraft radio was not in existence to any extent when we were there. There may be interference between amateur operators and airmen radio stations, and there will not be.

Mr. Sanders: Government ownership has nothing to do with that problem.

Lieut. Cooper: Government ownership would probably be operating the stations for aircraft.

Mr. Sanders: It is a question of which you speak of which may arise hereafter is a thing that will be met by appropriate regulations.

Lieut. Cooper: It might be be, sir, if this amend-

ment is past, that it might have to be met by legis-
la
tion
gainst the wave length back where it is now.

Mr. Sanders: Appropriate legislation?

Lieut. Cooper: It might be legislation and not regula-
tion.

Mr. Sanders: Legislation is just that much more author".

Lieut. Cooper: I usually think of "regulation as a regulation of a department.

Mr. Sanders: I admit that is so in general, where you think of something issued by some de-

PARTMENT, or some Bureau Chief, you bene-

Learn Public Speaking

10 LESSONS FREE

Write — quick — for particulars of this extraordinary offer; an opportunity you will never forget if you take advantage of it. Ten lessons in effective public speaking absolutely FREE to those who act promptly, to introduce our course in localities where it is not already known.

We teach you by mail to become a powerful and convincing speaker—to influence and dominate the decisions of one man or an audience of a thousand. We have trained hundreds and helped them to increase their earnings and their popularity. Learn, in your spare time at home, how to overcome "stage fright" and conquer fear of others; how to enlarge your vocabulary; how to develop self-confidence and the qualities of leadership; how to RULE others by the power of your speech alone; how to train your memory.

WHAT THE COURSE TEACHES YOU

How to talk before your club or lodge;
How to address board meetings;
How to propose and respond to toasts;
How to make a political speech;
How to tell entertaining stories;
How to make after-dinner speeches;
How to converse interestingly;
How to write better letters;
How to sell more goods;
How to train your memory;
How to enlarge your vocabulary;
How to develop self-confidence;
How to acquire a winning personality;
How to strengthen your will power and ambition;
How to become a clear, accurate thinker;
How to develop your power of concentration;
How to be the master of any situation.

New Easy Method

perfeeted and taught only by Prof. R. E. Pattison Kline, former Dean of the Public Speaking Department of the Columbia College of Expression, can be learned in 15 minutes a day. Prof. Kline is one of the foremost authorities in the country on public speaking and mental development. Do not let this chance escape you.

Offer Limited

SPECIALISTS IN DESIGN AN DCONSTRUCTION

You benefit by mentioning the “Electrical Experimenter” when writing to advertisers.
was merely an automation endowed with power of movement, responding to the stimuli of the sense organs and thinking and acting accordingly. The practical result of this is a perfect automaton which has been so far carried out only in an imperfect manner. Its latent possibilities will, however, eventually be shown. I have been since years planning self-controlled automata and believe that mechanisms can be produced which will act as if possessed of reason, to a limited degree, and will create a revolution in many commercial and industrial departments.

I was about twenty years old when I first succeeded in banishing an image from my vision by willful effort, but I never had any control over the flashes of light to which I have referred. They were, perhaps, my strangest experience and inexplicable. They usually occurred when I found myself in a dangerous or distressing situation, or when I felt that my situation or intellect was in some way being exaggerated. In some instances I have seen all the air around me filled with tongues of living flame, but of diminishing, with time and seemingly attained a maximum when I was about twenty-five years old. While in Paris 1888, a prominent French manufacturer sent me an invitation to a shooting expedition which I accepted. I had been long confined to the factory and the fresh air had a wonderfully invigorating effect on me. On my return to the city that night I felt a positive sensation that my brain had been given a light as a small sun was located in it and I past the whole night applying cold compressions to my tortured head. Finally the flashes diminished in frequency and force but it took more than three weeks before they wholly subsided. When a second invitation was extended to me my answer was an emphatic NO!

These luminous phenomena still manifest themselves from time to time, as when a new idea opens up possibilities strikes me, but they are no longer exciting, being of relatively small intensity. When I close my eyes I invariably observe first, a background of dark uniform blue, not unlike the sky on a clear but starless night. In a few seconds this field becomes animated with innumerable specks of green, arranged in several layers and advancing towards me. Then there appears, to the right, a beautiful pattern of two parallel lines of parallel and closely spaced lines, at right angles to one another, in all sorts of colors with yellow-green and gold predominating. Immediately thereafter the lines begin to move, brighter and the whole is thickly sprinkled with dots of twinkling light. This picture moves slowly across the field of vision and in almost every variant to the left, leaving behind a ground of rather unpleasant and inert grey which quickly gives way to a lillows sea of clouds, seeming to breathe and mould themselves in living shapes. It is curious I cannot project a form into this grey until the second phase is reached. Every time, before falling asleep, images of persons or objects fit before my view. When I see them I know that I am about to lose consciousness. If they are absent and refuse to come it means a sleepless night.

To what an extent imagination played a part in my early life I may illustrate by another brief experience. Like most children I was fond of jumping and developed an intense desire to support myself in the air. One day, just after lunch, I found myself charged with oxygen blown from the mountains rendering my body as light as cork and then I would leap and float in space for a long time in a delightful sensation and my disappointment was keen when later I undeceived myself.

During that period I contracted many strange habits, some of which I can trace to external impressions while others are unaccountable. I had a

Learned $200 in Four Months

This is the old K. A. Oldham. He earned $2,000 a month in four months with a Haywood Tire Repairing outfit. For 20 years he was a clerical worker on the Illinois Central Railway. He is now 45 years old. He answered an advertisement he saw for a tire repair position, bought a shop and opened a business. He was making $100 a month within six months and $600 in two years. Now in eight months by 21 years as operator.

There are now 500 stations where the tire repairing is neglected.

I Must Have 500 Men
To Fill These Positions

I have a list interesting book to send you. It tells all about tires—prices inside figures and profit. Send for it. We treat you absolutely. The men are doing you can do. $500.00 to $5,000.00 per year is possible. Write today.

Like Mr. Oldham. One machine will start you. Then you may expand. Cut out a Haywood sign and hang it on your door. You may get free samples for the big book and start making money.

YOU CAN’T AFFORD TO BE WITHOUT THESE BOOKS:

How to Behave

"Art of Pleasant Men." "How to Be

Do Without" is a wonderful book, packed with practical lessons. A man who can read this book will be a man to be envied.

W. A. Engle, 3297 Bishop St., Cincinnati, Ohio.

violent aversion against the earrings of women but other ornaments, as bracelets, pleased me more or less according to design. The sight of a pearl would almost give me a fit but I was fascinated with the glitter of crystals or objects with sharp edges and plano-spherical surfaces. I would not touch the hair of other people except, perhaps, at the point of a revolver. I would get a fever by looking at a peach and if a piece of camphor were placed in the house it caused me the keenest discomfort. Even now I am not insensible to some of these upsetting impressions. When I drop a little square of paper in a dish filled with liquid, I always sense a peculiar and awful taste in my mouth. I counted the steps in my walks and counted the cubic contents of soup plates, coffee cups and pieces of food,—otherwise my meal was unenjoyable. All repeated acts or operations I performed became second nature and if I mist I felt impelled to do it all over again, even if it took hours.

Up to the age of eight years, my character was weak and vacillating. I had neither courage or strength to form a firm resolve. My feelings came in waves and surges and vibrated uneasily between extremes. My wishes were labile and consuming force and like the heads of the hydra, they multiplied. I was oppressed by thoughts of pain in life and death and religious fear. I was swayed by superstitious belief and lived in constant dread of the spirit of evil, of ghosts and sprites and other unholy monsters of the dark. The more I seemed at one time, the more became a tremendous change which altered the course of my whole existence.

Of all things I liked books the best. My father had a large library and whenever I could manage to get a hold of my satisfaction for reading. He did not permit it and would fly into a rage when he caught me in the act. One day I ventured when he was off and found that I was reading in secret. He did not want me to spoil my eyes. But I obtained tallow, made the wick and cast the sticks into forms, and every night would burn the keyhole and the cracks and read, often till dawn, when all others slept and my mother started on her arduous daily task. On one occasion I came across a novel entitled "Abai" (the Son of Aba), a Syrian translation of a well known Hungarian writer, Jolna. I worked some how awakened my dormant powers of will and I began to practise self-control. At first my resolutions faded like snow in April, but in a little while I conquered my weakness and left a pleasure I never knew before—that of doing as I willed. In the course of time this vigorous mental exercise became second nature. At the outset my wishes had to be subdued but gradually desire and will grew to be identical. After years of such discipline I gained so completely a mastery over myself that I toyed with passions which have meant destruction to some of the strongest men. At a certain age I contracted a mania for gambling which greatly worried my parents. To sit down to a game of cards was for me the quintessence of pleasure. My father led an exemplary life and could not excuse the senseless waste of time and money in which I indulged. I had a strong resolve but my philosophy was bad. I would say to him, "I cannot very well. I have so much work to do, I can only make use of it worth while to give up that which I would purchase with the joyes of Paradise? On frequent occasions he gave vent to his anger and contempt but my mother was different. She understood the character of men and knew that one's salvation could only be brought about thru his own efforts. Once I had lost all my money and was craving for a game, she came to me with a roll of bills and said, "Go and enjoy yourself. The sooner you lose all the better it will be. I know that you will get over it." She was right. I conquered my passion

Skinderviken Transmitter Button

See what the editor of Electrical Experimenter says about the button:

J. Skinderviken, National Hotel,
Washington, D. C.

In writer's opinion, obtained by actual tests, your Transmitter button is the most efficient device of its kind on the market today, due in its simplicity and other outstanding features. Should have a great future, I understand.

H. Gernsback.

See what a couple of Electrical Experimenter reader says about the button:

New Brighton, Pa.

December 16, 1918.

Dear Sirs:
I have been using one of your Transmitter buttons for experiment work, and the price, $1.00, is well, for it is anything up to all you say for it and then some.

Yours truly,
Harry R. Brown.

Wash., D. C.

December 16, 1918.

Dear Sirs:
I received the Transmitter Button and I am well pleased with it. It is far better than what I claim it to be and more too.

Yours truly,
C. A. Wick.

We have now thousands of buttons in stock and can ship same day as order is received. Send remittance with order as per our money back guarantee. See our ad page 734.

We have large stock of necessary supplementary equipment for experimenting. Send for a complete list. Receivers $1.00. Induction Coils $0.35. Kingers from $0.35. Generators from $1.75.

TEN TELEPHONE OR FORTY TELEGRAPH CURRENTS OVER ONE CIRCUIT.

POSTMASTER GENERAL BURLINGTON, on December 12th, made public a letter from Theodore N. Vail announcing the invention and development by the technical staff of the Bell system of a new method of multiplex telephony and telegraphy, which is expected to revolutionize long-distance wire communication.

Mr. Vail, who is President of the American Telephone and Telegraph Company, explained that there can be a combination of ten telephone conversations or forty simultaneous telegraph messages together on one pair of wires. Each pair of wires a total of five telephone conversations are simultaneously operated, each giving service as good as that provided by the circuit working in the ordinary way.

Herefore the best telephone methods known to the art provided only one telephone conversation at a time over a single pair of wires. About a hundred years ago there was developed the phantom circuit arrangement, by which three telephone circuits were obtained from a pair of wires. This was an important improvement, of which extensive use has been made commercially. Now, by the multiplex method we are enabled to obtain five telephone circuits over one pair of wires, that is, ten simultaneous telephone conversations from the two pairs of wires which formerly could be used only for a single simultaneous telephone conversation. This means an increase of more than three-fold in the telephonic capacity of the wires, as compared with the best previous state of the art.

Some proposals made by the earlier workers in this particular field have naturally covered many of the successes of the solution of the problem, particularly a suggestion made by Maj. Gen. George O. Squier, Chief Signal Officer of the United States Army, ten years ago, which at the time attracted very general attention.

Furthermore, while working in entirely different fields and with a different objective, Dr. Lee deForest a number of years ago invented a wireless device known as the Audion, which by improvements and adaptation has been made an important part of the Bell telephone system.

Become an Electrician In One Year Here
Or Learn An Electrical Trade In 6 Months

THIS school teaches electricity thoroughly, from the very fundamentals, including the laws and principles of electricity and the theory of direct current—together with practical lectures and problems, actual training in laboratory work and electrical machine departments of designing, building, repairing, installing, operating, etc. And the faculty here are practical electricians who know how and what to teach because they know what knowledge and ability the great field of Electricity requires.

As one example of this school's thoroughness and practical training and development, witness the picture above, showing view of armatures winding department, where students actually wind armatures—D.C. and A.C.—by a most successfully practical and unique method.

The thoroughness in essentials here, the practical training and able faculty, together with this school's broad facilities and extensive addition, are the reasons why you can become an Electrician here in one year, or master one of the Electrical Trades in 6 months.

If you are determined to achieve success in the Electrical Field this is your school. You will acquire and accomplish more in a shorter time at a less cost and be a fully developed, practical electrical man when you finish. Mail the coupon now and get complete illustrated and descriptive details of the advantages this school affords. If interested in Electrical Engineering with B.S. degree, check same on coupon.

Mail the coupon now.

You Can Earn While You Learn

We will provide you with part time employment to help defray your expenses here and give you actual outside experience—without interfering with your class hours—which is fully explained in our catalog. Mail the coupon now.

CURING SOLDIERS' ILLS WITH ELECTRICITY

(Comment from page 695)

were 3,000 shell-shock victims; the day the
armistice was signed 2,000 of them re-
covered, showing what a peculiar and
balancing mental aliment this is.

The photograph on page 2 was taken at
the American Red Cross War Hospital, lo-
cated at Paignton, Devon, France, which
is one of the finest and best equipped in the Red
Cross service. This hospital has a staff of
150 nurses under the direction of Army
medical officers. The photograph shows a
soldier undergoing the electric bath treat-
ment for rheumatism. This treatment is
given in the massage room at the hospital,
where multiform other electric machines
and apparatus are found, in-
cluding electrical massage vibrators, electric
heating pads, etc.

In some of larger base hospitals, very
elaborate electric equipment has been
made available. In some of the American
Army hospitals in the United States, where
the returning wounded are being carefully
attended to, so as to make them as well and
strong as they were when they went overseas
to fight the Boche, there are some of the
very latest in instruments and apparatus
about which little is known outside of the
medical profession. This equipment in-
cludes among other things the Electro-car-
diograph, which is an extremely
sensitive galvanometer, capable of
recording the beats of the heart on a pho-
tographic film, so that the exact condition
of the heart with regard to its manner of
beating and its strength, can be minutely
and accurately studied by the physicians.

At one of the largest declaration
hospitals everything is done by
electricity—even to the cooking. This hospital
has one of the largest X-ray laboratories
in the world, each X-ray rooms
being equipped with a special dark room for
rapidly developing and finishing the X-ray
plates. The X-ray in itself has undoubtedly
saved thousands of lives from great con-
lict, in many cases when the victims of
bullet and shell wounds would certainly
have died, had it not been for this wunder-
ful scientific machine. Owing to the
terrible fragmentation (splintering) of the
shell now used, which often causes small
shrapnel splinters to penetrate parts of the
body where they would never be suspected,
and which, if they were not quickly dis-
covered by the X-ray, would be quite li-
able to affect the heart, lungs, or blood vessels
at some unexpected time and cost the victim
his life. For this reason the returning
wounded are most minutely examined and
X-rayed, especially in the abdomen and
chest regions, where many of these shell
splinters, and even bullets, are found
and podged themselves until the play itself makes
the meaning clear. To wit: "The first epi-

SALES MAN

Need to Get Peace-Time Orders to Keep Plants Busy

$2,500 to $10,000

A Year for Salesmen

Factories everywhere have been working day
and night on war contracts. With peace re-
turned, these factories must turn to peace-
time work. War contracts require no salesmen.
Peace-time orders must be produced by sales-
men. Salesmen will be the most vital factor
in business. Factories backed by best salesmen
will be the winners. To meet their demands
they will command practically their own price. Prepare now for this most essential peace-time work.

Let Us Make You a

STAR SALES MAN

We taught B. C. Kline—formerly earning $75 a
month—how to earn $750 a month as a sales-
man. We taught C. W. Harrington—former clerk
at $30 a week—how to earn $750 a month as a
sales manager. We taught George W. Keen—formerly earning $90 a
month (after 8 years) how to earn $750 a
month as a sales manager. Our simple course teaches the exact laws of
success. We tell you how to get more sales from 100 men than
they had ever made. You will learn how to
practically your own price, so you can earn what you were born to earn.

sode of the last act occurs before the last episode of the preceding act.” It simply means that at that critical time the action is going on in two places at once: and because the stage cannot jump back and forth in a flash like the motion picture, part of the story has to be postponed until the scene shifts elsewhere.

The illustrations which we present here-with are, of course, doctored up for the reader, assuming if they were not nothing at all it would be seen. It is very necessary to show the pictures in this manner, otherwise we would revert back to our camouflaged frontispiece,-the blank, spacey cover,-nothing,—and as the Editors must show pictures—well you know how it is:

A little camouflage here and there is often mightier than the pen!

EXPERIMENTAL MECHANICS. (Continued from page 717)

much more difficult than the ordinary run of lathe work. Fig. 5 shows how a crank pin, 1, with its rods, is set to be revolved between centers 2, 2, of the lathe. This is made with provisions for attaching to the crank rod 4, 4, temporary support plates 5, 5, that the crank shaft, and interconnecting center hoes in the plates in line with the center of the crank pin to be turned. The main D, D, must be turned first, then the second one finished. The plates 3, 3, must be bored out to be a tight fit on the ends of the crank shafts, to which they are further secured by a set screw as indicated. The crank pin is then laid on a surface plate or on the lathe bed, which will answer this purpose very well, and the centers of the crank pin, 1, determined and carefully marked on the supporting plates, 3, 3, so that when mounted between lathe centers the axis shall pass thru the central axis of the crank pin. The center holes should be drilled and countersunk in the usual way at these points, and each shaft may then be mounted in the lathe on its centers, and one end secured to the face plate with a dog and the crank pin turned to proper size.

It will be found in turning crank shafts that the work as a whole is very much out of balance, and a counterbalance weight on the opposite side is the driving of the lathe. This work will be of interest to those building engines, etc.

(To be continued)

PRODUCING RAIN BY ELECTRICITY AND X-RAYS. (Continued from page 687)

valve rectifiers, is used to produce the high potential current for operating the X-ray tube, and this current is fed to the tube thru the two wires leading up to the bellows. The X-ray tube itself is placed in a light-water-proof compartment suspended from a spar just below the balloon, as the illuminating shaft shall be seen. When used, the Röntgen-ray tube is so hung that the rays are directed upward, so as to impinge upon the metallicized surface of the balloon, which, as will be remembered, is charged at a very high potential. Suitable high voltage, strain insulators are placed in the lead wires at all the points shown. A recording instrument, such as a hot wire ammeter is connected in series with the high tension lead wire. If the ground switch is closed, then any leaky charge in the neighborhood of the balloon is conveyed to earth, and all conditions are obtained on the instrument. When the ground switch is opened, the air surrounding the balloon for a radius of several hundred feet is endowed with conductive qualities as a result of the emanations from the X-ray tube. When the ultra-high voltage

Pay Raisers

These books are written by well-known authorities—the top-notchers in each line. They tell you exactly the points you make more money. You can't fail to understand them, because they are written in plain, everyday language. They are filled with thousands of photographs, diagrams, charts, etc., to help you make difficult points as simple as A-B-C.

Ask Our Experts

With these books you can free of all charge a $12.00 Consulting Membership in the American Technical Society. If any question puzzles you—write us. Our corps of experts and engineers will solve any problem. Ask all the questions you want for a whole year. This service is absolutely FREE.

Don't Send Any Money!

Write the name of the books you want on the coupon and mail it today. We will send the books at once, express collect, and you can use them just as if they were your own for a whole week. If you decide you don't want to keep them, send them back at our expense. If you like the books, as thousands of other men have after examination, just send us $2.00. You can send the balance of the special reduced price the same way.—$2.00 each month (50 cents a week). Start right now and learn to fill bigger shoes. There will be a better job looking for you if you do. Be ready to meet it when it comes. Send the coupon now.
ELECTRICAL ENGINEERS $1 HANDBOOK

HERE'S just the book on Electricity that you need to answer your many questions. It tells you the Knotty problems, to teach you new kinds, to be your ready for tables, rules, formulas and other Electrical and Mechanical facts that some people try to make you dig up and tell.

With this "Little Giant" I. C. S. Electrical Engineer's Handbook in your pocket, throttle on your work bench, drawing table or desk, the day need not be all "digging up" some forgotten rule, some unfamiliar fact. You'll just turn to the very complete index and get it in "a jiffy." Just a few of the subjects treated are:

Electricity and Magnetism: Electrical Symbols; Batteries; Circuits; Magnets; Direct and Alternating Currents; Dynamics and Motors; Relays; Switching; Electrotyping; Electrical Measurements; Motors; Arc and Incandescent Lamps; Mercury Arc Rectifiers; Transformers; Insulation; Electric Cars; Single and Multiple-Unit Control; Rail Welding; Tables of Sizes - Sizes, Capacities, etc., - Magnetic Properties, Symbols; Tables of Constants, Equivalents, Roots, Powers, Reciprocals, Areas, Weights, and Miscellaneous.

The Electrical Engineer's Handbook is one of 116, C. S. Handbooks covering 91 Technical, Scientific and General subjects. It is an excellent book to have in your home, office, or workroom. It is pocket size ready to go with you anywhere and at any time. Put it in your pocket and you'll find it invaluable. Keep a copy in your desk, and you'll find it invaluable. If you wish to return the book, your money will be refunded.

ELECTRICAL COMPANY

128 South Eleventh Street, Philadelphia, Pa.

Charging circuit is closed and the metallized balloon surface electrified, then the air in the vicinity of the balloon receives a powerful electronic charge, which acts on the aforesaid particles, suspended or floating in the air in the manner aforementioned. The inventor has been engaged for many years in the design, construction, and operation of electrical apparatus and means for application against lightning discharges.

The inventor mentions that two or more operating stations for rain production may be used in cooperation, depending upon the observed meteorological conditions, these stations being located at considerable distances apart. In operating multiple stations the degree and sign of the charges used therein, respectively, may be varied as required. The effect of ultraviolet rays instead of Röntgen rays for ionizing the atmosphere is discussed by Mr. Balsille in the description of the apparatus, but they are of little practical interest, as he points out, for they produce practical ionization effects only when reflected from a fluorescent surface.

EXPERIMENTAL CHEMISTRY.

(Continued from page 71)

will contain crystalline deposits. Some of the sublimat will be amorphous.

(THE CARBON TEST).--In this the Arsenious Oxide is reduced by Carbon [CO being formed] to metallic Arsenic, which sublimes as in Marsh's Test.

HYDROGEN SULFID TEST.--The hydrodor sulfid solution, [AsS] [Yellow] from an acid solution of any arsenic salt.

2AsCl + HJ.S = AsS + HCl.

Physiological Effects.

Like other arsenical compounds, the oxide is very poisonous, the lethal dose being about 2% gram. It is called an Irri- tant poison, and acts rather slowly, as the digestive fluids have to transform it before absorption. The antidote is freshly prepared ferric hydrat (Fe(Oh)3), together with Magnesia. 2FeCl + 3Mg[OH] = 2Fe(Oh)3 + 3MgCl.

This forms a compound of arsenic insoluble in the fluids of the body, and precipitated in the stomach, etc. An overdose may act as a purgative.

For evidence of arsenical poisoning in post-mortem examination of the liver, the stomach, etc., these organs and their contents are sometimes analyzed before the Marsh and other tests can be applied, in order to separate the arsenic from the vessels and food products. After being treated with HCl, KClO, etc., the finely divided substances are put into a dialyzer (a parchment membrane, see Fig. 150), and suspended in water, when the arsenic compounds, being more diffusive, pass through the membrane in the water of the outer vessel, leaving the other substances behind. This water is then concentrated, and tested for arsenic. Generally, however, the contents with the arsenic are dissolved in aqua regia and then tested by Marsh's or Reason's test.

Use.

It is employed in shot manufacture to give a globular form to the shot. Cobalt Glance, a compound of Arsenic and Cobalt, has considerable use as fly-rose under the name of Fly-stone. Arsenic also finds use in many rat poison compounds.

TESTS FOR ARSENIC.

Marsh's Test.

ELECTRICITY! $1

AGAIN OPEN TO CIVILIANS

FOR A QUARTER OF A CENTURY this institution has been training men for the electrical industries.

SINCE JUNE 15, 1918, the School has been filled to its maximum capacity, and detailed by the War Department to receive an intensive course of instruction for electrical positions in the service.

DUE TO THE CESSATION OF HOSTILITES by the War Department, we have discontinued this work. We will, therefore, resume our CONDENSED COURSE IN ELECTRICAL ENGINEERING, JANUARY 15, 1919. This 26th class is now recruiting.

The school is provided with approved dormitories, dining hall, excellent laboratories and shops, all thoroughly equipped throughout. A judicious combination of theory and practice results in a well-balanced course.

Because of the demand for admission EARLY APPLICATION is necessary. Catalogue on request.

ELECTRICAL EXPERIMENTER

February, 1919

DO YOU WANT A Wonderful Muscular Development, with perfect health and strength of vitality and great strength? Just pay all your bills, if you want them, and I can show you any time of my system are shown on my own person and that is recommendation enough.

New book, "Muscular Development," GET THE BOOK AND BOOK IT TO benefit you. A copy of this book will send you a book on that. We send the Catalog, 20c. Please write for a Booklet, FREE.

EARLE L. RUBENSTEIN, 239 Broadway, New York City

ELECTRICAL EXPERIMENTER

Don’t Be a Sickly Failure

Are you dragging yourself out from day to day, always tired and dispirited; suffering from backache, indigestion, constipation; or feeling especially well? you have to be a man again. You can be full of life and energy and good health; you can trample on the sickly troubles that are pulling you down. If you can change the water fluid in your veins, you will have more and more blood, and body, more strength in your lull, and you can get rid of that eternal languish and fatigue feeling and start you on the path to success.

I Can Re-Create You

I know that I can make you serviceable to you 100 per cent., because I have helped and am helping thousands of other men in the same position for years, before they took our Strongfort. I have no pains, no want of energy or stamina to offer no such experience, the full experience of a lifetime. This is the only plan which has given me freedom, and you can quickly acquire it. I shall then be free to take up health and strength and mental and physical vigor and efficiency.

It’s Never Too Late

Strongfort doesn’t know the meaning of the words "too late." No matter what your age or condition; no matter how long you have been mired in the slough of despondency or struggling under the handicaps of physical and mental loss. Strongfort can make a new man of you. Strongfort can improve every part of your system; strengthen your heart, lungs, liver, stomach; clear your brain; steady your nerves; rid you of that eternal languish, tired feeling and start you on the path to success.

Send for our Free Book

"Promotion and Conservation of Health, Strength and Mental Energy" tells you all about Strongfort; tells you how you can overcome your mental and physical disabilities and get the full value of your own魂s, and how to attain the perfect body you really are. It tells you, in detail, how to attain the strength of a horse. The book is free. Write for a copy.

The Oliver Typewriter Co.

672 Oliver Typewriter Bldg.,

Chicago, Ill. (0.00)

A USEFUL ELECTRICAL LABORATORY SWITCH-BOARD.

(Continued from page 715)

are fifteen contacts and they should be spaced about 3/4" apart. The construction is

shown in Fig. 8. The rods in both the transformer slide and the rheostat are

mounted on a hardwood or fiber block, the dimensions of which are shown in figure

9. The rod is fastened to the block by means of screws or by a long pin thru the

entire rod and block. The handle is fastened by bending a piece of brass as

illustrated in the side-view. The contacts are six in number and are 3/4" thick 1/4" long

and 3/4" wide. Each marble with No. 8—32 flat-head machine screws counter-

sink into the contacts. Make them extend far enough behind the board to serve as

contacts. The roller heads must fit snugly because they will have to carry 60

ampere of current.

Next we will take up the construction of the transformer. The dimensions are given in

Fig. 6. The core is built of No. 28 sheet iron or stove pipe iron will do. The pieces are

cut 5 x 1 1/2" and 2 1/2" x 1 1/2". Use enough to build a core 1 1/2" thick when

comprest. For 110 volts consist of 380 turns, 290 turns on each of No. 18 D.C.

The secondary consists of 180 turns of No. 14 or better No. 12 D.C. Taps are

brought out at every 300 turns and at every additional five turns until the tap

for 10 volts is brought out. Then bring out taps at the 60th turn, the 90th, 120th,

150th, 180th and 195th turns. These are connected to the transformer contacts and the beginning of the coil is connected to one side of the

plug receptacle. The other side of the plug receptacle is connected to the brass rod.

But the transformer must be mounted first. Figure 7 shows how this is done.

The rheostat is made of No. 18 iron wire on 6 wooden cylinders three inches in diameter and 12 inches long. Wind 29 ft. of wire on each. Use nails or screws to hold the winding. Connect in series and immerse in water. Tap the iron wire connections between each coil by using brass or copper wire and be sure to let the copper make the connection below the water. If the water gets too low the wire will almost instantly melt if it is carrying full 60

ampere. The connections are much the same as those of a starting box. Connect one side of line to rod and the other side to the 50 amperes stage plug; connect other terminal of stage plug to last lead of rheostat and connect the first terminal or beginning of the coil. No. 1, beginning of second coil to second contact, etc.

The main-line wires must be No. 1. This wire is the expensive—switch-board must or rather should be near the entrance cut-out.

A 100 amperes current at 110 volts is 11 K.W., and if you mean the transformer supplying your house must be of that capacity. 

Don't Wear a Truss

BROOKS APPLIANCE, the modern development, the wonderful new discovery that relieves rupture will be sent on

trial. No obligations, springs or pads. Puts automatically the internal structures in the right relation. Can be used to form any kind of a fluid. Bands and draws the broken parts together as it would a real Truss. No nails. No iron. Dur-
The Boy's Electric Toys

EXPERIMENTERS!
A Sample of What You Can Do With This Outfit

This illustration, made from an actual photograph, shows only a very few instruments that can be made with the Boy's Electric Toys: Electromagnet, Electric Pendulum, Electric Telegraph, Current Generator, Electric Telephone, Pencil Cases, Spiral, Galvanized Iron, and others. Space does not permit us to show the hundreds of experiments that can be performed with this wonderful outfit.

The Outfit contains 114 separate pieces of material and 24 pieces of finished articles ready to use at once.

Among the finished material the following are included: Chromic salts for battery, lamp socket, bottle of mercury, core wire (two different lengths), a bottle of iron filings, three spools of wire, carbon, a quantity of machine screws, flexible cord, two wood boxes, glass plate, paraffine paper, binding posts, screw-driver, etc., etc. The instruction book is so clear that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the layman with all of the most important facts in electricity in a simple manner.

We guarantee satisfaction.

The size over all of the outfit is 14x2x5% inches. Weight, 8 lbs. No. EX2002 "The Boy's Electric Toys" as described.

IMMEDIATE SHIPMENTS

The "Electro" Radiotone

HIGH FREQUENCY SILENT TEST BUZZER

This instrument gives a wonderfully high pitched MUSICAL NOTE in the receiver, impossible to obtain with an ordinary buzzer. The RADITONE is built upon entirely new lines. It is NOT an ordinary buzzer, reconditioned in some manner. The RADITONE has a single coil, high pitch, superior, being of the highest speed, adjusted to its most efficient frequency at the factory. Hard drive contacts are used to make the instrument last indefinitely forever.

Yes, the RADITONE is SILENT. In fact, it is so silent that you must place your ear on it to hear its beautiful musical note.

You will be astounded at the wonderfully clear, 500 cycle sounds, owing to the high frequency of the receiver. Outfit works with all the recent Radiotone, and one dry battery. The RADITONE is the ONLY instrument for that purpose on the market. No metal parts are exposed inside, and contact with the receiver is made by a screw, not by touching the receiver itself, but by using a separate cord of rubber. No. EX2002 "The Electro" Radiotone.

IMMEDIATE SHIPMENTS

The "Electro" Codophone

(Patents Pending)

What this remarkable instrument is and does.

The "Electro" Codophone is a positive new instrument made only to make your friend's Wireless Code phon Exclusively with this instrument. Its excellence and beauty are in the picture of the Codophone illustrated. It will make any Wireless receiver.

The "Electro" Codophone is a true talking receiver equipped with a horn, talles so loud that you can hear the talk of all the receiver, even if there is a lot of other noise.

THAT'S NOT ALL. By using a Codophone receiver, a note from the lines, even a whisper, or a whisper, is picked up, and the speech can be heard in a room.

For INTERCOMMUNICATION. Using two dry cells each, one instrument, the Codophone will make any Wireless set highly efficient when the wires and rooms connected with the "Electro" Codophone. Even a whisper is picked up, and the speech can be heard in a room.

One outfit alone makes one of the finest Codophone instruments. The "Electro" Codophone is a handsome, well made machine, the finest instrument, tool, and built for hard work. Contacts are of hard silver, 1/4 inch in diameter, that will support the instrument.

One outfit alone makes one of the finest Codophone instruments. The "Electro" Codophone is a handsome, well made machine, the finest instrument, tool, and built for hard work. Contacts are of hard silver, 1/4 inch in diameter, that will support the instrument.

There is also a neat code chart and booklet accompanying the Codophone, and any ten-cent postcard may be used.

Order today, please. Net $2.00. Shipping Weight, 3 lbs.

ELECTRO IMPORTING COMPANY
231 Fulton Street, NEW YORK!
MT. WILSON'S HUNDRED-INCH TELESCOPE.
(Continued from page 703)

detailed description of the process of figuring the mirror. Roughly speaking it may be divided into two stages. In the first stage the mirror was brought to a spherical figure, and in the second this spherical form was charged to paraboloid. The second process the requiring much more time than the first, involved great care and frequent optical tests to avoid the introduction of zonal errors. The largest deviations from the paraboloid form in the sphere in the case of this mirror is only one-thousandth of an inch. All of the optical work, with the exception of the first rough shaping, has been carried out with wooden tools of various sizes and forms, and the use of rouge and distilled water as the polishing material.

After the completion of the mirror a series of photographic tests made was to determine the accuracy of its figure. These showed a remarkably high degree of perfection, every part of the surface having the same focal length to within one part in about 90,000.

A few figures may be of interest in this connection. The finished mirror weighs 414,800 tons, about one ton of glass having been removed in the process of shaping and figuring. Its diameter is closely 101 inches, and its thickness at the edge 13 inches. The depth of the curve at the center is about 114 inches. The focal length of the mirror is five times its aperture, or 42 feet. At the center of the moon at this focus, accordingly, would have a diameter of 4.4 inches. As in most modern reflecting telescopes, the mirror will be provided with two small convex mirrors to be attached to the upper end of the tube, either of which may be employed to increase the focal length in much the same way as telephoto lenses are used in ordinary photography. With these mirrors focal lengths of 34 and 251 feet may be obtained and the magnification correspondingly increased.

As soon as the optical work upon the mirror disk was finished the sign of every way of the telescope mounting was begun. In view of the great size and the immense weights involved the "closed fork" type was finally adopted. This form of mounting the telescope tube is hung in the center of a rectangular frame of massive steel girders, the bearings providing for north and south movements of the tube being built into the two side members. The entire rectangle is mounted on bearings at top and bottom, which furnish the east and west motion of the telescope. To relieve friction the system of mercury flotation used most successfully for the 60-inch reflector is employed, there being two large steel floats and corresponding mercury tanks, one at each end of the rectangular axis. These floats are about 98 per cent of the moving parts of the telescope, or some 50 tons, the remaining two per cent being carried by two large spherical defining lens. The instrument is completed by electric motors, which provide for three rates of speed in both north and south and east and west directions.

The driving clock, which moves the telescope at a uniform rate corresponding to the rotation of the earth is placed within the concrete pier which supports the instrument and makes movements of the driving shafts. From the clock and meshes with a worm wheel 17 feet in diameter, which is attached to the telescope 34, 58.

The building and dome which enclose the telescope form a steel structure 100 feet high and 95 feet in diameter. The walls and roof are double throught to admit of the free circulation of air, and thus to keep the temperature within the building. The shutter of the double section type, divided in the center, and when fully open provides an aperture 2 feet wide. Like the observing platform, the crane hoist and the dome mechanism, it is operated by electric motors. The dome is mounted on 24 four-wheeled trucks resting, for the most part, on ground rails, and power is applied by two driving trucks at opposite sides. When rotated the motion of the dome has been found to be remarkably smooth and free from vibration in spite of the great weight involved, which is approximately 600 tons.
Opportunity Adlets

You will find many remarkable opportunities and real bargains in these columns. It will pay you to read and investigate the offerings made by reliable dealers and manufacturers for automobile accessories, the opportunity to make money, or anything else, you will find listed here the best and most attractive special offers of the month.

Advertisements in this section are subject to the above restrictions. No advertisement may exceed one inch in width and seven lines in length. No service fees are charged advertisers. Ten percent discount for 6 issues, 20 percent discount for 12 issues from above rate. Objectionable or misleading advertisements not accepted. Advertisements for March issue must reach us not later than January 22.

The Circulation of the Experimenter is over 100,000 and climbing every month.

Charlette, N. C.

Oct. 4, 1918.

Dear Sirs:

It certainly was SOME RESULTS.

For your information, I have enclosed about $8.00 in stamps from China. Shanghai can you beat it! I'm enclosing a check for $3.00 to collect.

I'm a-goin' guil, and will never do it again, or at least I won't promise to answer all the letters that I hear about a "Deal that I put in the "E. E."

Desperately want a Bicycle to come in. The apparatus advertised has long since been sold. The agents are from all over the United States, AND ELSEWHERE. I'll be out of sight from Shanghai, China. Can you beat that. I'm enclosting five cents for your trouble.

It's a great life, if you don't weaken. I wish to THANK the "E. E."—Some circulation.

Very Respectfully,

JAMES MATHERS,
403 N. Brevard St., Charlotte, N. C.

ELECTRICAL EXPERIMENTER

EXPERIMENTAL CHEMISTRY. (Continued from page 751)

3. The burning of hydrogen. 4. Burning of arsin. 5. Breaking up of arsin by heat. The solution of arsin in sodium hydrosulphite gives:

\[ 2\text{As} + 5\text{Na}_2\text{SO}_3 + 3\text{H}_2\text{O} = 2\text{H}_3\text{AsO}_3 + 5\text{NaCl}. \]

In the same manner as above, test some solution imagined to contain arsenic.

**Experiment No. 149.**  
Perform an experiment using SchC solution in exactly the same way as the AsCl was used, and compare the results. Pay particular attention to the difference between Sulfuric Acid and Deposition, in color, and in solubility in NaOCl.

**Reinisch's Test.**

**Experiment No. 150.**  
Pour into a dish 3 or 4 cc. of a solution of arsenic chlorid (AsCl) or sodium arsenit (NaAsO), added with hydrochloric acid. In this solution place a strip of bright copper foil (about 3 cm. x 4 cm.) and boil the liquid for three or four minutes—longer, if no discoloration of the copper appears.

What is the color? No change in the copper indicates absence of arsenic. In that case shake more HCI and boil again. If the copper is finally darkened, take it from the liquid with the forceps, rinse it carefully, and press it lightly between the folds of filter paper to remove moisture. Then cut it into small strips with scissors; drop these strips to the bottom of a long and narrow test tube, and slowly heat the lower part of the tube.

See whether the copper changes color. Look for a sublimate. State its color; its position in the tube; its appearance, like the sublimate in Marshall's test? Compare it with metallic arsenic, arsenious oxide, etc. Examine the sublimate under a microscope and scratching off a little for this purpose. Is it crystalline or amorphous?

**Experiment No. 151.**  
Make arsenious sulfit (As₂S₉), wash it free from impurities, dry it and put it away for future use.

**Experiment No. 152.**  
Ascertain by experiment a solvent for arsenious sulfit (As₂S₉). Try (NH₄)₂CO₃.

**Experiment No. 153.**  
Make Paris Green (Cu₂AsO₄·11H₂O), wash, filter dry, and put away for use.

**Experiment No. 154.**  
Make arsenious oxide (As₂O₃), using not over ½ gram.

**Experiment No. 155.**  
See whether As₂O₃ is at all soluble in water.

Examine the various compounds of arsenic with special regard to colors—red, yellow, green, and white—and attach names.  

(To be continued)

**JAPAN HAS WIRE-WIRELESS CENTRAL.**

An exchange to wireless and wire telephones is to be established in Kobe very shortly by the Government Department on Communication. A copy of the Japanese newspaper in Japan port will be connected by “Are you there?” girls with the telephones of subscribers in Kobe, Osaka, Kyoto and neighboring cities, thus serving the most densely populated section in Japan.

Handy Pocket-Size Volumes

Just what you need to know to succeed in ELECTRICITY

Every electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in simple words a complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your every day work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, and way of doing things electrically. Every subject is indexed so that you can turn right to it. There are a study course and a reference guide in one, written in plain every day language—no wasted words—neither do you need a name—check full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handily bound in flexible black covers. You can carry each volume with you until you have mastered its contents. 1,000 pages of actual information and 4,700 illustrations. Once you see these books and put them into actual use you will never again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books. To look them over—ask them all the questions you can think of. Take them to your work—study them—pick up some ideas; you will ship you the entire set of 10 volumes entirely FREE. This is an offer a card of our confidence in the guides. Pay gold does not object to being tested. Keep them for seven days and if you do not desire that you can't alone without them, return them to us and use us nothing.

When you decide to keep them you only have to pay $1.00 down and remit the balance of $9.00 on the next payment of $3.00 a month till paid for.

Use this coupon to get the books. It will pay you many times over.

How Violet Ray Benefits

Electricity from your light socket is transformed into health and beauty-giving Violet Ray—powerfully effective, yet gentle, soothing, perfectly safe. Voltage is raised from ordinary lighting current to several hundred thousand volts, giving tremendous penetrative force. The tremenous, revitalizing powers of Renulife Violet Ray are applied at once to every nerve cell, fibre and part of body. Blood is enriched and purified by a flood of oxygen, giving added vitality and strength. Assimilation and digestion improved—functions restored to normal—extra supply of fresh blood quickly brought to area treated, removing congestion and supplying nourishment. While relieving pains and aches, the manifest results of disorders, it removes the deep-seated cause; combines the benefits of electricity, vibration, exercise, stimulation and oxidation.

Painless Electricity

Science has modified electricity that the weakest may stand its force without fear or pain. Every tissue and fibre is saturated, patient experiencing only a sensation of relief, as if standing in a ray of sunshine. Violet Ray high frequency has no comparison with old, crude electrical batteries and shocking current. Every jar and shock is removed. The effects are marvelously rapid. Relief can be given in one or more treatments. Often cures are accomplished in that time. It is positive and certain in action. If you value your health, and want to keep or restore your good looks and gain vitality, throw away medicine bottles—take this sensible, scientific means. Violet Rays work with nature. Every day's delay makes relief more difficult.

EXPERIMENTER

SCIENCE AND INVENTION

SEARCH LIGHTS

OF THE DEEP

SEE PAGE 772
Thousands of Electrical experts are needed to help rebuild the world. Come to Chicago to the great shops of Coyne and let us train you quickly by our sure, practical way, backed by twenty years of success. Hundreds of our graduates have become experts in less than four months. You can do the same. Now is your big opportunity. Come—no previous education necessary.

Earn $125.00 to $350.00 A Month

In the Electrical business. Come here where you will be trained in these great $100,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

No need of taking from 1 to 4 years to become an expert, we have proved this in thousands of cases. The Coyne method of practical training eliminates all books, useless theory and other non-essentials and trains you in just what you need to know to become an expert.

Day or Evening Courses

Don’t worry about the money. Anyone with ambition can learn here. Our tuition is low with small easy payments if desired. All tools and equipment is furnished free. Our students live in comfortable homes in the best section in Chicago—on the lake.

EARN YOUR WAY

Many students earn a large part of their living expenses by doing a little work in their spare time. Our employment dept. furnishes these positions without charge.

BE A COYNE

Trained Expert. Our Graduates are given the Preference. They are in demand Everywhere at big Salaries.

Our graduates are in demand because Coyne is known for its splendid practical training. We are continually receiving letters, telegrams and telephone calls from contractors, manufacturing firms, etc., seeking our graduates to fill responsible positions. We often have many more positions than we can fill and the demand is steadily growing.

LEARN DRAFTING

Skilled Draftsmen are always in demand. Our courses are thorough—short—practical, preparing a man fully to hold a position of responsibility. We have more positions than we can fill. We also have thorough practical courses in Plumbing and Heating and Motion Picture Operating.

Send Today for Book
Write today, now, for the book. It tells what Coyne graduates have done. What you can do. Fill in the coupon, check the trade you are most interested in or send a postal card, do it now.

The best investment of the year—

CROFT'S ELECTRICITY

Get at the first-hand facts about electricity, taken from work itself.

This is the year of big things in electricity. Don't waste any time in getting ready for the big pay that awaits the electrically trained man. Don't depend upon amateurish or theoretical books or courses to give you the necessary knowledge. Books written from practice by practical men are easiest mastered, and when you do master them, you are an expert, ready to demand the salary of an expert.

KNOW ELECTRICITY AS EXPERTS KNOW IT

You can now say to yourself "If others are earning $5,000 per year and up in electrical practice, I can also do it, because Croft's Library contains the same information that those men possess."

Croft's Library does contain just the information you need to reach the big position. It contains all the information you need in electrical practice. Nothing is left out. You are told of every detail in plain language and illustration.

Not one of the thousands of men who own the Croft Library has said he could not understand the books. They are as clear as the elementary readers and arithmetic you studied in school. And yet they are thorough, and do not leave off until you are an expert. They are just as valuable to the beginner as to the highest paid specialist, because they are all practice.

No one interested in any branch of electricity, or who expects to take up the work, can afford to be without Croft's Library.

8 Beautiful flexibly-bound volumes, pocket size, 3000 pages, 2100 illustrations

These eight handy, compact volumes are a work of art. Carefully indexed for quick reference and for study. Every one of the subjects are literally at the finger's end. No turning of pages for what you want.

Not one cent in advance. Merely return the coupon above. Small monthly payments if you are satisfied.

Don't wait another day if you want to know electricity as experts know it. Fill in the coupon now. We will ship the eight volumes charged for ten days' examination. Return them at our expense if they are not entirely satisfactory. Pay only $2 per month for eight months if you are pleased.

ACT NOW
Underground Wireless

By H. Gernsback.

But the most spectacular feature of Mr. Rogers' revolutionary invention probably is his "Sub-sea Wireless." Scientists the world over, Marconi included, declared it an utter impossibility to communicate by wireless with a totally submerged submarine. Mr. Rogers, however, has carried his theory this far ahead and does it, not with fresh water but with salt water as well. Indeed he established wireless communication with a submarine whose aerial wires were laid below the surface of the ocean.

Altho Mr. Rogers, during the war, gave most of his attention toward receiving messages, he has made considerable progress in underground radio transmission as well. His experiments prove conclusively that, while underground radio receiving is here to stay, underground sending too will soon be practical enough, even for high power stations. It is merely a question of good insulation at present, and the end of this year, we are quite confident, will bring the solution of the problem. The Navy Department has just succeeded in transmitting a distance of 30 miles with the underground system.

And it would seem a reasonable thing that any long wave lengths could be used with the Rogers system. But this is not the case. Underground Radio-telephone messages, several miles distant, come in just as clear on 30 meters wavelength as does the Nauen (Germany) station with 12,000 wavelengths of wave length. This indeed is good news for our amateurs.

But in the meanwhile, all of our pet theories on wireless are thrown in a sad chaos. For we do not know as yet how the Rogers system works. We can now expect a war to the knife between our wave-propagation theorists and the new school of ground-impulse savants. Mr. Rogers himself takes the view—and he is seconded by Tesla—that the transoceanic messages which he receives over his underground system are not Hertian waves pure or even converted—but merely high frequency ground impulses.

The future may tell us which school is right.
How One Evening’s Study Led to a $30,000 Job

A Simple Method of Mind Training That Any One Can Follow With Results From the First Day

By a Man Who Made Formerly No More Than a Decent Living

I HOPE you won’t think I’m conceited or egotistical in trying to tell others how I came to be comfortably off. I am not trying to show to what my friends term a phenomenal success.

In reality I do not take the profit to myself at all. It was all so simple that I believe any man can accomplish practically the same thing if he learns the secret, which he can do in a single evening, I assure him. I was not so much the beneficiary as the reader, as I had done much better than I by following the same method.

It all came about in a rather odd manner. I had been worrying along in the same way as the average man thinking that I was doing my bit for the family by providing them with three square meals a day, when an old chum of mine, Frank Powers, whom I had always thought was about the same kind of a chap as I, suddenly blossomed out with every evidence of business prosperity.

He moved into a fine new house, bought a good car and began living in the style of a man of ample means. Naturally the first thing I did was to notice these things and then I realized that I had said nothing to me about his sudden good fortune—was to congratulate him and ask him what it was that had brought the evident change in his finances.

"Bill," he said, "it’s all come so quickly I can hardly account for it myself. But the thing that has made such difference in my life lately began with an article I read a short time ago about training the mind.

"I compared the average person to a bank and its contents as it went along, which carried any distance would arrive at its destination practically empty."

It brought to my mind that instead of making the pail leakproof most of us kept filling it up and then lost all we put into it before we ever reached the place where the contents would be of any real use.

David M. Roth

When Mr. Roth first described to me his highly successful method of mind training, I was a little worried about its profit to me. But I was overly worried about my memory one way or another, but it had always seemed to me that important things fairly well. Certainly it never occurred to me that it was possible or even desirable to improve it, as I thought the memory was a sort of natural gift. Like most of us, I imagined training to be something that was something that had been too long and that I had no assurance that until it was written in a memorandum pad or in a pocket notebook. Even then I would sometimes forget to look at my re- membered facts. I had happened to be one who had not been—by being obliged to ask some man whom I had previously met that my name was a sort of natural gift. Like most of us, I imagined training to be something that we should know before it is written in a memorandum pad or in a pocket notebook. Even then I would sometimes forget to look at my re- membered facts.

"And still," he continued, "I was a little worried about my memory one way or another, but it had always seemed to me that important things fairly well. Certainly it never occurred to me that it was possible or even desirable to improve it, as I thought the memory was a sort of natural gift. Like most of us, I imagined training to be something that was something that had been too long and that I had no assurance that until it was written in a memorandum pad or in a pocket notebook.

I began to observe myself more closely in my daily work. The frequency with which I had to refer to records or business letters always impressed me with the feeling that I was getting something that in some previous time had come under my particular notice."

The men around me were doing things that I had not been doing."

"But I did not use this feeling to train my mind as it was about the matter of the memory power."

F. W. Thomsen

Mr. Roth ran and has hundreds of times at different times and places asked himself, "What do you mean?"

"I was never met to tell him his mind was the same."

"And then," he continued, "I was an acquaintance with the mind and in the way the things that are going to be useful to him as he goes along.

Farther on in the article it was stated that the power of the mind is like a battery, and that the things that go on in the mind are like the power of the battery."

Mr. Roth says, "What I have done any one can do."

I had reached my decision. On the recommendation of experts, I got in touch with the Independent Corporation which shortly before had published the David M. Roth Method of Memory Training, and thus came the surprise of a lifetime. In the very first lesson of the course I found the key to a good memory. Within thirty minutes after I had opened the book the secret that I had been in need of all my life was mine. Mr. Roth had boiled down the principles perfectly the way I had thought the method could not be grasped at a glance. And the farther I went, the more I thought that I had learned that method and reliable your memory becomes. Within an hour I found that I could easily memorize a list of 100 words and call them out in order without a mistake. I was thunderstruck with the ease of the thing. Instead of study the whole thing seemed like a fascinating game. I discovered that the art of remembering had been reduced by Mr. Roth to the simplest mode of learning. It required almost nothing but to read the lessons! Every one of those seven simple lessons gave me new powers of memory, and I enjoyed the course so much that I look back on it now as a distinct pleasure.

The rest of my story is not an unusual one among American business men who have realized the value of a reliable trained memory. My income today is close to $30,000. Many decisions involving thousands of dollars are made by me every day, and I enjoy every moment of the process."

SEND NO MONEY

Mr. Roth’s fee for personal instruction to classes limited to any member is $1,000. But in order to secure nation-wide distribution for the Memory Course, the Independent Corporation will send without charge the price at only five dollars, a letter containing the secret of a good memory to one evening, that they are willing to send the Course on free examination.

If you send any money. Merely mail the coupon or write a letter and the complete course will be sent, an charge prepaid, at once. If you are not entirely satisfied send it back any time within five days after you receive it and you will not have to pay for it."

The only course that will give you a secret of a good memory is in one evening, that they are willing to send the Course on free examination.

* On the other hand, if you are as pleased as we are the thousands of other men and women who have used the book, and are glad to have such a wonderful book, you take no risk and you have everything to gain in sending for it."

FREE EXAMINATION COUPON

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
Master Electricity By Actual Practice

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

The Oldest and Only Institution of the Kind in America

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

Over 5,000 Graduates are Successful Men in the Electrical World

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions.

Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you

33 Assembled Locomotives on One Ship

The Enterprise of American War Engineering Which Enabled Thirty-Three Assembled Locomotives to be Delivered 'Cross Seas in a Single Ship, for Immediate Duty at the Front

ERN persevering American ingenuity and the knowledge that "over there" thousands of our boys were depending on us folks back home, to keep our shoulders to the wheel, makes records of the seemingly impossible to get supplies across seas infested with mines and submarines, and still a greater task to move this material with all possible haste to the points where it would be most needed. It is well known that the French railroad system had collaps; all it could do of his first cables home was for the urgent delivery of locomotives, cars and rails. He made the War Department see the need of providing these facilities so that the American effort in the Great Cause would not be a failure. And so it was that Army officials

deeds actually accomplished, read like the magic of Aladdin's Lamp.

As a specific instance, let us look at the railroad situation in France when General Pershing arrived on the scene of action with the first vanguard of American troops. French Atlantic ports were nearly 270 miles from the fighting front. It was one problem to care for the French army, and to move the thousands of tons of material necessary for the successful campaigning of Pershing's army behind a few creeping French locomotives left at our disposal was well nigh impossible.

General Pershing saw the immediate need for American railroad equipment and one undertook the buying and shipping of locomotives. The first locomotives sent were in great big boxy cases—knocked down. As yet they did not dream of sending them completely assembled.

Once these parts reached France they were put in the hands of a dozen or more (Continued on page 810)
Five Conversations Over One Wire

Multiplex Telephony and How It Works

The story of the development of the multiplex telephone and telegraph system reads like that of many other inventions. It is a story of long years of effort to accomplish a great result. The steam turbine, for example, is but recently developed to be practically useful and was suggested in principle as long ago as 130 B.C. Dr. Alexander Graham Bell was experimenting with a telephone in a Boston attic in 1875. Its possibilities lie in the direction of expansion of long distance service. Physically it can be employed on any open wire telephone line, but practically it is not advantageous to use it on any short line, say less than 100 miles in length. The highly technical equipment required is so costly that it is economically available only for long lines. There is at now it has been carrying messages, which come to Baltimore from Washington over the ordinary circuits and these are given to the multiplex for transmission to their destination.

For some years past the Bell System engineers have sought to make it possible for anyone to talk to anyone else in another part of the country at any time. The phantom circuit, which utilizes wires in two ordinary circuits to provide a third conductor of speech, was a great step forward this goal, greatly expanding the service possibilities of existing long lines. Then came transcontinental telephony, making a real neighborhood of the Nation. Now, with the multiplex system, the engineers greatly expand the service capacity of all long lines which economically may be equip with the system. The three transcontinental circuits, for example, two of which are of wire while one is a phantom circuit, when equipped with the multiplex system can carry 10 telephone conversations at once, instead of 3 as at present. The new system sends five voice currents simultaneously over one telephone circuit of two wires, each current as it is delivered into an ordinary telephone, exactly as it was formed at the sending point. These five voice currents travel together and are sorted for delivery at the destination. Not a tone or inflection of the speaking voice is changed in passage. This result is achieved by combining each voice with a high-frequency audible carrier current which has characteristics in degrees of frequency that are entirely different from those of other carrier currents. See the various forms of the voice and carrier currents shown herewith. The carrier current (Continued on page 826)
The Latest Style in Flashlights

A pocket flashlight with its small, one-half or one-quarter power tungsten bulb operated by a small dry battery, has practically become a household article the world over. Flashlights are today manufactured by the million, while more millions of people are daily clamoring for them. The progress of millions of flashlights was in constant use during the war-time activities in Europe, and what a great boon it has been to the soldier can well be imagined. The accompanying illustrations show a number of extremely useful and not always well-known applications of the pocket flashlight which will prove of practical use on many occasions.

One of the latest and ingenious arrangements for utilizing a flashlight is that shown at Fig. 1, which comprises an illuminated note-pad for use at night or in dark places. The use of this illuminated note-pad will prove very extensive undoubtedly, and for the use of Fig. 1 it may often prove of assistance in taking notes at lectures, not to mention a very wide application in the Army and Navy. The illumination is so arranged that no noticeable glow is seen, but simply the illuminated square opening over which the paper roll slides. A second paper roll is included, so that a carbon copy can be kept for record. The case when closed resembles a kodak.

Figure two shows a self-contained electric light mirror, invented by Mr. H. Herschbeck several years ago. This unique mirror has a small flashlight battery placed in the hollow handle. On the front of the handle a push-button is placed and the wires to the lamp at the top of the mirror frame are secreted within it.

Figure three shows the gun-light which has been quite extensively exploited, and while we have never heard of it the sight of a flashlight or a larger model flashlight attached to a rifle, we have seen the pistol flashlight used. It proves one of the most deadly combinations imaginable.

All the marksmen have to do is to move the pistol about until the target lies in the center of the subdivided flashlight zone and then pull the trigger. It should prove a fine thing for hunting down burglars, rats, cats, and what not.

A recently patented eye-diagnostic lamp, known as a retinoscope is illustrated in Fig. 4. This compact and efficient electric lamp and mirror, as well as a sight device for the use of opticians in examining the eye. The flashlight battery is contained in the handle of this efficient instrument, and the bulb of the flashlight projects a beam of light on to the small mirror, which is set at an angle of 45 degrees. Turn the center of this mirror there is a small hole which is in line with a sight tube at the rear of the mirror frame. It is used in the manner illustrated.

The well-known flashlight combination, known as the shave light, is shown at Fig. 5. Several varieties of this handy device are on the market and it has proved a blessing indeed to thousands of soldiers—officers and dough-boys alike—who have often had to shave in dingy or pitch dark dug-outs and other places of shelter on the battle-field. In the shave-light device illustrated by Fig. 5, the flashlight battery is connected by means of a small flexible twin-conductor with a lamp bulb placed over the mirror.

One of the latest and most practical ever-day uses of the flashlight is meter-reading. See Fig. 6. The usual application of the flashlight in this field involves the carrying of an ordinary tubular flashlight by the meter reader, but the illustration herewith shows one of the newer developments in the form of a flashlight meter camera. With this clever device it is only necessary to place the camera before the meter to be read, the button is pressed, several flashlight bulbs connected in multiple throw a strong light on the meter dials, the camera-shutter clicks simultaneously, and (Continued on page 831)
“The Border Wireless” and
“The Hun Within”

STEVE RANSOM (William S. Hart), a typical March, has shot fierce assistant, attacked telegraph and unaware for younger the Yellow Dog. Elsa Miller is a telegraph operator at United States. Steve forces Brandt to kiss the American flag. War with Germany is declared, and Steve determines to enlist. He calls on Elsa, determined to reveal his past love to her, and invites her to ride part of the way with him to Fort Scott; she plainly evinces her love for Steve. During their absence Steve’s shack is ransacked by Brandt and Schloss; photographs of Steve’s father with an inscription on the back, reveals the fact that Steve’s real name is Ransom, and not Allen—which name he assumed while in Yellow Dog. Brandt sends a telegram to the Sheriff at Willow Springs, asking for information regarding other spy ride by. They go thru his clothes and find the message, which is translated with the aid of a code book. Carl, who has regained consciousness, overhears the translation of the message, the purport of which is that General Pershing is on his way to Europe and the Germans are planning to sink the vessel on which he has sailed. The two men take their departure, leaving their man to watch Carl. Elsa now appears and Carl whispers to her the nature of the message. The German, hiding behind the bushes, overhears Carl and is about to shoot him, when Steve, who has been hiding in the bushes.

Yellow Dog, and the guardian of her younger brother, Carl. Elsa is on her way to deliver a message to Herman Brandt at the Magdelenas Mines and is attacked by Mexican bandits. Steve rescues and falls in love with her and decides to remain at Yellow Dog. Frederick Brandt loves Elsa, but she is unaware that the Magdelenas Mines have been converted into the headquarters for German spies with a cleverly concealed wireless apparatus by which messages are transmitted to Mexico and from there to Honduras and then to Berlin. Brandt is in direct communication with Von Helm, head of the German Secret Service in New York City.

Steve becomes suspicious of Brandt, when he and his assistant, Frederick Schloss, express contempt for the American flag and the fighting abilities of the Steve and thus learns that Steve is a fugitive from justice. Carl reveals the fact that Steve is on his way to Fort Scott to enlist, and Brandt forces the boy to telegraph the commanding officer at Fort Scott the facts he has discovered regarding Steve. While awaiting examination at Fort Scott, Steve overhears the conversation between the commanding officer and the telegraph operator, and makes his escape through a window. He is pursued by the soldiers but eludes them and takes refuge in a wooded canyon. Elsa learns of the occurrence, but this does not shake her faith in him. A day or two later, a code message comes for Brandt, and Carl starts with it for the Magdelenas Mines. He is thrown from his horse and is lying unconscious, when Brandt and Schloss and another man attempt to kill him. Carl, who has regained consciousness, reveals the message, which is translated with the aid of a code book. Carl, who has regained consciousness, overhears the translation of the message, the purport of which is that General Pershing is on his way to Europe and the Germans are planning to sink the vessel on which he has sailed. The two men take their departure, leaving their man to watch Carl. Elsa now appears and Carl whispers to her the nature of the message. The German, hiding behind the bushes, overhears Carl and is about to shoot him, when Steve, who has been hiding in the bushes.
M ost probably you will remember having read some of those entrancing fairy tales in your younger days, wherein a person happened to be gifted with such transcendental intellectual powers, that he could for example stamp his foot on the ground or simply make a certain sound when the location of gold or silver would immediately be made known and found. Of course this all sounds like "Bu-lgar-ia" to us nowadays, but thanks to a twentieth century magician, Prof. R. A. Fessenden, the brilliant American inventor and scientist, it has become possible to do this identical thing, i.e., to project a sound wave, and by measuring its refraction and reflection scientifically by means of suitable detecting and recording instruments, to locate exactly the position of underground ore bodies, no matter what the ore may be, whether gold, silver, lead, zinc, copper, etc.

As Prof. Fessenden points out in his patent on this scheme of locating ore bodies, his invention fairly tells its story and apparatus whereby, being given or having ascertained two or more of the following quantities, i.e., the distance, the intensity and medium, one or more of the remaining quantities may be determined. For example, being given the distance between two points in a mine, and having determined the time required by a sound wave to travel between the two points, it is then possible to draw calculations in regard to the probable nature of the rock between the two points; also, if an echo be observed or a refraction of the sound, it is possible to estimate the distance of the reflecting or suspected, a space may be laid off about five miles square, as the accompanying illustration shows. This gives an area of twenty-five square miles under survey. At each corner of this square there are driven four drill holes, A, B, C, D, which are filled with water. Toward the bottom of these water filled holes there are placed sensitive sound detectors, such as microphones or small Fessenden oscillators, D, D, D, and D. These sound receiving devices are connected to the secondaries of transformers as indicated, and to oscillographs of the photographic recording type. These oscillographs employ the quartz-fiber Einthoven galvonometers. In one of the wells there is placed a powerful sound producing apparatus, O, preferably of the Fessenden oscillator type also. This is connected thru its leads, with the primaries of the transformers in the oscillograph circuits and to the alternating current dynamo, A—D, whenever the key K is depressed. Hidden ore detectors or microphones, D, D, D, and D, and is recorded on the oscillographs R—O's, 3, 4, 2 and 1.

Instead of using the alternator to produce the sound at the oscillator, O, a condenser discharge may be employed to actuate a sounder, the condenser key on being depressed charging the condenser from a battery, and on the key being released and coming against a second contact, it discharges the condenser thru the sound producing mechanism. The patent describes this auxiliary sound producing mechanism.

Since the oscillograph photographic strip moves along thru the machine with a regular and known velocity, the distance on the strips between the records produced thru the transformers whenever the key, K, is depressed, and the records made by the sound waves received, whether direct or by reflection, refraction or echo, will indicate the distance between the drill and holes and

(Continued on page 828)
Sorting Tobacco Leaves by Electricity

By GEORGE HOLMES

ANY ingenious machines and devices have been invented and are widely used in the manufacture of tobacco products and all modernly equipped cigar and cigarette factories bristle with machinery. The more striking is the fact that the tobacco growers and planters have been much neglected by the genius of inventors. Thus we see that tobacco is grown today with the same primitive methods as it was 100 years ago.

The inventive spirit of our progressive age, which benevolently gave a helpful lift to almost every trade and industry and helped so many labor-saving appliances to agriculture, has almost neglected the extensive tobacco plantations of America and the world.

Upon the initiative of one of the largest tobacco growers in the world, a New York inventor and engineer, Mr. H. Hartman, took up the problem several years ago of tobacco planting and handling right at the farms. And what he saw there set him to thinking that one of the most costly operations at a tobacco plantation is the sorting of leaves by their different lengths. Every leaf is taken by hand at both ends and measured and placed according to its length into a different box.

So-called sun-grown tobacco is usually sorted or “sized” by two inches, while shade-grown tobacco, which is used for wrappers, is “sized” partly by inches and partly by two inches. This work is done after the leaves have passed thru the “curing” process and are brown, soft and pliable.

Now anyone can easily imagine the tremendous amount of manual labor involved in measuring each single leaf of the many millions grown on an average tobacco farm. But the tobacco can not be sold if not sorted into different lengths.

After many experiments with three gradually more and more improved machines, which Mr. Hartman constructed at his workshop and laboratory, he finally succeeded, and the semi-electric “Leaf Tobacco Sizing and Sorting Machine”, illustrated here is the result. This machine also marks as a milestone the opening of tobacco growing to mechanical development.

In this machine, which is also shown diagrammatically, the tobacco leaves are simply placed upon a feeding belt by an operator in front of the machine. This belt brings rollers, which stand vertically in the path of the motion of the clamps. As long as a leaf is between the contact rollers, a metallic electric contact between the latter is prevented, but a low voltage circuit will be closed thru the moment the tip of the leaf passes out. As the contact rollers are co-operating with a series of contact segments arranged at the center line along the bench, one of these segments will be swept by a contact brush from the clamp in circuit with the rollers. An electric current will then pass thru the rollers, said particular segment and one of a number of solenoids will attract its armature and thus open one of the covers, which can be seen arranged under an incline at both sides of the machine.

At the same time an electromagnet will emerge from the flat table and, being in the center line with the clamps, will force the latter to open, and to drop the leaf upon the table, from where it will be blown the next moment by compressed air over the entire table and slide by gravity downward to fall into the box arranged below the open cover. According to the length of a leaf, a certain contact segment on the table will be in circuit with the contact rollers only at the moment said leaf passes entirely thru the rollers, and only that particular cover connected with said segment will open, as intermediary relays will at the same moment interrupt for a predetermined time the connection between all following segments and their respective solenoids.

There are as many segments and solenoids as there are different covers. The first section, having five boxes, will receive the five shortest leaves. If a leaf is longer, no segment will come into contact in said first section, the electro-magnetic stop will not appear and the clamp will carry that leaf into the second section where the same process will be repeated. The second section provided with five boxes of longer dimensions, is an exact

PERHAPS you are familiar with the mechanical device known as a "gyroscope", which possesses remarkable self-centering or stabilizing properties. The Sperry airplane stabilizer, as well as the non-rolling ship stabilizer, utilizes this clever device. It involves the simple phenomenon that if you take a heavy steel or other wheel and spin it at high speed, then the spinning wheel and its attached frame will tend to preserve the same plane of rotation. This is daily demonstrated by the ordinary bicycle. Hold the bicycle clear of the ground and have someone turn the pedals rapidly. Now try to turn the bicycle sidewise while the wheels are rotating at high speed. You will find it very difficult—all because of the law above stated. Thus the naval engineers have discovered that by placing one or more powerful gyro's in a ship, that the ship will not roll to any appreciable extent in a heavy sea. Hospital and war-ships are therefore being fitted with giant electric driven gyro's for the purpose of keeping them on a more even keel in stormy weather. The improvement in gunnery from warships so equipped and stabilized is readily apparent.

One of the accompanying photos shows Gyro unit No. 2 of the twin set just being transferred by a hundred-ton S-3 leg crane. A second photo shows a close-up of the two Gyro units, while the third photo shows the relative size of the Gyros with the ship and also the massive traveling crane used to swing them into the ship. These gyro's were installed in a Naval Hospital ship so that the wounded on board would be subjected to the least amount of rolling, that to the present time is very apparent on all ships, especially in bad weather. The final stabilizing test with the Gyros was found to reduce the rolling some 90 degrees, which can be readily seen that they do help some.

The combined weight of the unit was 100 tons and the ship was the largest hospital ship ever constructed. The weight of the two gyro wheels is 25 tons each. The weight of the two casings is 25 tons each. The diameter of the gyro wheels is 9 feet, and of the casings 12 feet. The bearings used are standard roller type and self-aligning, fitted to 12-inch shafts. The power used to drive the gyro wheel is a 75 H.P. A.C. electric motor in each. The casing was made absolutely vacuum-tight and the gyro runs in 20 inches of nearly perfect vacuum. The bearings receive a continuous bath of oil, pumped at the rate of 200 gallons a minute, properly screened and cooled. In 35 minutes the gyro attained a speed of 1,100 R.P.M. (working speed). A trial speed of 1,600 R.P.M. was attained, the current cut off and the gyro ran for three and one-half days, gradually dropping in speed to "Dead".

The side of the ship had to be cut away in order to install the gyro's and they were slid into place by means of skids; the time required to slide them into place was 71/2 minutes. Besides the 75 H.P. A.C. motor in each gyro, a rotary-converter is used and another 75 H.P. motor is used to process the gyro's from left to right to meet the roll of the ship. This last motor is controlled by another sensitive gyro (small and of high speed) located on the ship's bridge.

The two gyro's were located amidships below medi-centric height and they ran in opposite directions to each other; that is, the port gyro ran clockwise and the starboard gyro ran anti-clock-wise, both at the same speed. To reduce the vibration of the gyro's to a minimum they were balanced by the plug-method and it took several experts two months to balance them, so perfect must the rotational balance be. Two years were required to complete the gyro's and others of larger size are being constructed for super-dreadnought warships. These will enable more accurate aim to be had in firing from the ship. Gyros of smaller size are also installed on submarines and destroyers, both classes of installations giving remarkable results.

gallium and silver sulfid were found to have but small photoelectric activity when charged to a negative potential and exposed to light. No change was observed in the electrical conductivity of tellurium, bismuth, pyrite, silicon, and mixtures of the sulfids of lead and antimony, when exposed to light. An increase in conductivity was observed in crystals of bismuthinite, cylindrite, molybdite, selenium, stibnite, boulangerite, jamesonite, and silver sulfid when exposed to light.

Experiments are described in which some of these substances were joined thru a battery to the grid circuit of an audion amplifier and a telephone. The light stimulus was interrupted by means of a rotating sector disk, as used in Bell's selenium photophone. When using a cell or crystal of selenium the fluctuations in light intensity produced a sufficient change in conductivity to cause a musical note in the telephone. Similarly, in some samples of bismuthinite and of molybdite, a change in conductivity was produced, which caused an audible sound in the telephone receiver. Further experiments are in progress to determine to what extent and for what wavelengths this is a true photoelectric change (increase) in conductivity, and to what extent it is caused by fluctuations in temperature with a resultant change in resistance within the crystal.
Searchlights of the Deep
Wonderful Fish of the Ocean Depths, That Carry Their Own Lights.

By Dr. E. BADE

In former years, when the depths of the ocean were still unexplored, it was the common belief that its surface was an uneven monotonous plain, unenlivened by precipices and mountains, hills and valleys. But these ideas have been thoroughly repudiated by numerous expeditions sent out to investigate and explore, as far as possible, the conditions existing at the vast bottom of the sea.

The higher parts of the ocean bed, the gentle slopes, the precipices, and the plateaux, which connect the extensive levels of the ocean, are of such an immensity that they can not be compared to anything found on the land. Deep basins of continental extent are interrupted by gigantic marine mountains, while table lands rise from the greatest depth with almost sheer and perpendicular walls.

Only those animals which live near the surface of the ocean and which have ventured within reach of the nets of fishermen, were known in the last century. These nets seldom if ever penetrate more than five hundred feet. But when speaking of the deep sea, a 1,000 foot depth or more is to be considered.

Altho depths of 12,000 feet are common throughout the ocean, a depth of more than 30,000 feet has been reached between two small islands of the Malay Archipelago.

Three hundred feet below the level of the ocean the light is so diffused that it is gloomy, and at a depth of six hundred feet our eye can not detect an infinitesimal ray.

Photographic plates sunk in the Sargasso seas show, at a depth of three hundred feet, all of the different colors of the rainbow; at a depth of 1,500 feet many of the rays can still be found; at a depth of 3,000 feet of water is equal to the pressure exerted by it. This pressure becomes greater the deeper we go down, and down in the profoundest depths it exerts a pressure of thousands of pounds to the square inch. A result of the pressure is that the tissues of the fish are loosely knitted together, and when this enormous pressure is released by bringing these denizens of the deep to the surface, the internal pressure of the body becomes so great that the fish literally explode.

Therefore it is no wonder that when the deep sea fish are violently torn from their natural habitat they are invariably in a mutilated condition.

But in these depths of the ocean, where gloom and semi-darkness prevail, the conditions of life are far different from those of the surface waters. The brightly colored algae and sea weeds, the food of many fish, are the children of the sun, while the sinister inhabitants of the profound depths are scavengers, which kill and devour each other.

The faint almost infinitesimal light which penetrates this utter darkness is insufficient to light up the paths of the fish. They do not see their way; they only feel their way by means of lateral organs when they come in the vicinity of some boulder or rock. In this darkness we find the most unique and fantastic forms of life—the deep sea fish—which live in perpetual darkness. There, searchlights play thru the watery night, faintly illuminating the vast depths with a cold, death-like glow, a thing man has, as yet, not created.

This wonderful light is produced automatically by the fish. Tiny glands secrete the lighting fluid, reflectors throw it outward, and one or more lenses magnify and control its intensity. (See the illustrations herewith.)

(Continued on page 830)
THE UPS AND DOWNS OF A THEATER CHAIR.

E said it, friends, "the ups and downs of a theater chair", and we might add the "downs and ups" for can you imagine in your wildest moments of philosophical ecstasy what our theaters are looking like when Mr. Frank Adsit's electrical elevated opera chair is adopted by our theater managers. No, you're wrong. This is not a phony patent, but an honest to goodness U. S. patent. Our artist has endeavored to show several of the incidents which might and likely will occur if this invention comes into vogue, and who will gainsay that it will—or have not forty-eight states—tried and true—gone clean dry without a whisper? This wonderful motor-operated theater chair is also a real boon to the prohibitionist inspector, for all he has to do is push the button and the occupants of the chairs will rise "high and dry" without a word. Coming down to the real philosophy involved in the design and operation of this newest theater chair, we find that the inventor has provided for causing it to rise and fall whenever a person wishes to pass in front of one of the chairs in order to get to his seat, to one side or the other, by means of three distinct electromechanical agencies, to wit: 1—by means of an electric motor and screw-gear; 2—by means of mechanically driven worms placed under the floor and screw gear; 3—by means of compressed air.

A small electric motor is connected with a pinion and gear which in turn drive a vertical screw in the base of the seat. This screw registers with an "internal nut" (so, Ella, not the "nut" in the chair) in the position of the chair as the detail illustration shows, so that when the screw is turned in one direction, the chair will be raised, and when it is turned in the other, the chair will be lowered. The running of the motor is positively controlled by the push button placed on the arm of the chair.

AN AMPHIBIAN LAND, WATER AND AIR HYDROPLANE.

The accompanying illustration shows one of the latest inventions in the realm of hydroplanes and this particular species might well be classified as an amphibian of the first water. As its inventor states in his patent, yes, he has really been granted a patent by Uncle Sam on this marvelous contraption—his airship may be used in the air, thru water or upon the land with equal facility. The inventor provides in his design for the combination of a lighter than air or buoyant flying machine with a water-tight passenger compartment. Thus he has given us a vehicle which may be used on inundated or marine surfaces, and the vehicle is further provided with wheels, in such a manner as to move readily over any ground surface. The machine is fitted with suitable motors, planes and rudders, all of which are accessible and controllable from the interior of the enclosed cab of the airship. This remarkable hydroplane should prove a great boon to the management of summer resorts, who are forever on the watch for something really new and novel. As our illustration discloses, a great variety of pleasure is afforded the passengers who embark on a voyage of adventure in this hybrid airship.

The superstructure consists essentially of a cylindrical metallic tube having a cigar-shaped front end and an outer wall formed of a number of longitudinal ribs, which are in turn connected to an inner encircling band, thus forming a substantial framework for the ballonets or gas bags, which are used to give the airship the desired buoyancy. The car attached to the superstructure and ballonet frame on the bottom, is provided with windows and doors, all of which may be sealed hermetically from the interior of the car, so that the car may be run thru the water, fully submerged, when desirable or necessary, and in any event the passengers are assured of a most delightful trip among the fishes.

At the rear end of the car is a revolving screw for propelling the hydroplane thru the water, while a rudder is also used to control the direction of the airship in its flight thru the water. On top of the ballonet superstructure, the inventor places two masts for the support of a radio antenna one of which may act as a flag pole.

You Must Not Fail to Visit the Summer Resorts This Year. They Promise to be More Alive Than Ever Before. For Example—Be Sure This Wonderful Amphibian of the Sea, Air and Earth. The Inventor Patented and Described Everything But the "Fare." Anyhow, We Are Going to Take Out "Accident Insurance Before Starting." (Continued on page 815.)

Bear, the Rising and Falling Electric Opera Chair. "It's a Hard Job to Keep the Old Man at Home Now." It is the Complaint of Some Wives, But Can You Imagine What Show Wifey Is Going to Have to Keep "This Nib" at Home by the Fire-side with His Slippers on. Three Booms and a Tiger for Inventor Adsit (at's it)."
PROBABLY one of the most far-reaching and revolutionary discoveries made by Mr. Tesla is the so-called rotating magnetic field. This is a new and wonderful manifestation of force—a magnetic cyclone—producing striking phenomena which amazed the world when they were first shown by him. It results from the joint action of two or more alternating currents definitely related to one another and creating magnetic fluxes, which, by their periodic rise and fall according to a mathematical law, cause a continuous shifting of the lines of force. There is a vast difference between an ordinary electro-magnet and that invented by Tesla. In the former the lines are stationary, in the latter they are made to whirl around at a furious rate. The first attracts a piece of iron and holds it fast; the second causes it to spin in any direction and

with any speed desired. Long ago, when Tesla was still a student, he conceived the idea of the rotating magnetic field and this remarkable principle is embodied in his famous induction motor and system of transmission of power now in universal use.

In this issue of the Electrical Experimenter Mr. Tesla gives a remarkable account of his early efforts and trials as an inventor and of his final success. Unlike other technical advances arrived at thru the usual hit and miss methods and hap-

hazard experimentation, the rotating field was purely the work of scientific imagination. Tesla developed and perfected, entirely in his mind, this great idea in all its details and applications without making one single experiment. Not even the

magnetic field was thus tested. The frequency of the two-phase A.C. current, which varied from 23 to 300 cycles, the best results being obtained with currents of from 35 to 40 cycles. This laboratory was lighted by a great number of lamps, some of which may be seen on the ceiling, and each of which emitted 50 C.P. Two coils resting on three legs and disposed in the immediate foreground to the laboratory, were connected with the primary circuit of the transformer which collected energy from an auxiliary circuit exciting the laboratory, no matter in what position the transformer was placed. A few tesla secondary of one or two turns of insulating cable (not visible) was provided for stepping down the energy collected by “mutual induction,” and supplied for various tests such as lamps, vacuum tubes, motors and electro-magnets. When the circuit around the hall was strongly excited, the secondary furnished energy at the rate of about three-quarters of one horse-power.

The usual first model was used. When the various forms of apparatus he had devised were tried for the first time they rotated exactly as he had imagined and he took out some forty fundamental patents covering the whole variation he had explored. He obtained the first rotations in the summer of 1883 after five years of constant and intense thought on the subject and then undertook
the equally difficult task of finding believers in his discovery. The alternating current was but imperfectly understood and had no standing with engineers or electricians and for a long time Tesla talked to deaf ears. But, ultimately, his pains were rewarded and early in 1887 a company bearing his name was formed for the commercial introduction of the invention.

Dr. Tesla recently told the editors an amusing incident in this connection. He had approached a Wall Street capitalist—a prominent lawyer—with a view of getting financial support and this gentleman called in a friend of his, a well-known engineer, at the head of one of the big corporations in New York, to pass upon the merits of the scheme. This man was a practical expert who knew of the failures in the industrial exploitation of alternating currents and was distinctly prejudiced to a point of not caring to even listen to several discouraging conferences Mr. Tesla had an inspiration. Everybody has heard of the "Egg of Columbus." The saying goes that at a certain dinner the great explorer asked some scoffers of his project to balance an egg on its end. They tried it in vain. He then took it and cracking the shell slightly by a gentle blow, made it stand upright. This may be a myth but the fact is that he was granted an audience by Isabella, the Queen of Spain, and won her support. There is a suspicion that she was more impressed by his portly bearing than the prospect of his discovery. Whatever it might have been, the Queen pawed her jewels and three ships and sailed for the New World. It so happened that the Germans got all that was coming to them in this war. But to return to Tesla's story. "Well," he continued, "what if I could make an egg stand on the pointed end without cracking the shell?" If you could, I would drown the news that you had gone Columbus one better. "And would you be willing to go out of your way as well as lose much time and no crown jewels to pawn," said the lawyer, who was a wit, "but there are a few ducats in our buckskins and we might help you to an extent."

Mr. Tesla thus succeeded in carrying the experiment a step farther. He knew—indeed the judges of the New York Exposition were impressed with the fact that he had given the world a new and valuable invention. They were asked by the counsel, "Do you want any money?" "Columbus," he said "never in a worse predicament," said the great inventor, who had parted with his last portrait of General Washington in defraying the expenses of the preparation. Before the meeting adjourned he had a substantial check in his pocket, and it was given with the assurance that he was to be had in the same bank. That started the ball rolling. Tons of millions of horsepower of Tesla's induction motors are now in use all over the world and their production is rising like a flood.

In 1893 Mr. Albert Schmidt, then Superintendent of the Westinghouse Electric and Mfg. Co., constructed a perfect rotating field ring with an egg made of copper, and larger than that of an ostrich, for Dr. Tesla's personal amusement at the Chicago World's Fair. This piece of apparatus was one of the most attractive novelties ever publicly shown and drew enormous crowds every day. Subsequently it was taken to Mr. Tesla's laboratory and served there permanently for demonstrating rotating field phenomena. It was practical to use as much as 200 horsepower for a short time, without overheating the windings and the effects of the magnetic forces were wonderfully fascinating to observe. This is the very ring indicated in the accompanying photograph (Fig. 1), giving a view of 3/4. The egg in the center was 32 inches in diameter, but Mr. Tesla transformed it to the three- and four-phase when desired. On top of the ring was fastened a thin circular board, upon which was provided a small disk around its circumference with a guard to prevent the objects from flying off.

Even more interesting than the spinning egg was the exhibition of planetary motion. In this experiment one large, and several small brass balls were usually employed. When the field was energized all the balls would be set spinning, the large one remaining in the center while the small ones revolved around it, like moonlets about a planet, gradually receding until they reached the outer guard and raced along the edge.

But the demonstration which most impressed the audiences was the simultaneous operation of numerous balls, pivoted discs and other devices placed in all sorts of positions and at considerable distances from the rotating field. When the currents were turned on and the whole animated with motion, it presented an unforgettable spectacle. Mr. Tesla had many vacuum bulbs in which small, light metal discs were pivotally arranged on jewels and these would spin anywhere in the hall when the iron ring was energized.

Rotating fields of 15,000 horsepower are now being turned out by the leading manufacturers and it is very likely that in the near future capacities of 50,000 horsepower will be employed in the field of other industries. Self-propulsion of Tesla's electric drive which, according to Secretary of the Navy Daniels' statement, has proved a great success.

But any student interested in these phenomena can repeat all the classical experiments of Tesla by inexpensive apparatus. For this purpose it is only necessary to make two slip ring connections on an ordinary small direct current motor or dynamo and to wind an iron ring with four coils as indicated in diagram Fig. 3. No particular rule need be given for the windings but it may be stated that he will get the best results if he will use an iron ring of comparatively small section and wind it with as many turns of stout wire as practicable. He can usually copy plate an egg but he should bear in mind that Tesla's egg is not as innocent as that of Columbus. The worst that can happen with the latter is that it might be broken, but the Tesla egg may explode with disastrous effect because the copper plating is apt to be brought to a high temperature from the induced currents. The sensitive experimenter will, therefore, first suck out the contents of the egg—thus satisfying both his appetite and thirst for knowledge.

Besides the rotating field apparatus Mr. (Continued on page 308.)
My Inventions
By Nikola Tesla

2. MY FIRST EFFORTS IN INVENTION

SHALL dwell briefly on these extraordinary experiences, on account of their possible interest to students of psychology and physiology and also because this period of agony was of the greatest consequence on my mental development and subsequent labors. But it is indispensable to first relate the circumstances and conditions which preceded them and in which might be found their partial explanation.

From childhood I was compelled to concentrate attention upon myself. This caused me much suffering but, to my present view, it was a blessing in disguise for it has taught me to appreciate the inestimable value of introspection in the preservation of life, as well as a means of achievement. The pressure of occupation and the incessant stream of impressions pouring into our consciousness thru all the gateways of knowledge make modern existence hazardous in many ways. Most persons are so absorbed in the contemplation of the outside world that they are wholly oblivious to what is passing on within themselves. The premature death of millions is primarily traceable to this cause. Even among those who exercise care it is a common mistake to avoid imaginary, and ignore the real dangers. And what is true of an individual also applies, more or less, to a people as a whole. Witness, in illustration, the prohibition movement. A drastic, if not unconstitutional, measure is now being put thru this country to prevent the consumption of alcohol and yet it is a positive fact that coffee, tea, tobacco, chewing gum and other stimulants, which are freely indulged in even at the tender age, are vastly more injurious to the national body, judging from the number of those who succumb. So, for instance, during my student years I gathered from the published necrologues in Vienna, the home of coffee drinkers, that deaths from heart trouble sometimes reached sixty-seven per cent of the total.

Similar observations might probably be made in cities where the consumption of tea is excessive. These delicious beverages super-excite and gradually exhaust the fine fibers of the brain. They also interfere seriously with arterial circulation and should be enjoyed all the more sparingly as their deleterious effects are slow and imperceptible. Tobacco, on the other hand, is conducive to easy and pleasant thinking and detracts from the intensity and concentration necessary to all original and vigorous effort of the intellect. Chewing gum is helpful for a short while but soon drains the glandular system and inflicts irreparable damage, not to speak of the revolution it creates. Alcohol in small quantities is an excellent tonic, but it is toxic in its action when absorbed in larger amounts, quite immanently as to whether it is taken in as whiskey or produced in the stomach from sugar. But it should not be overlooked that all these are great eliminators assisting Nature, as they do, in upholding her stern but just law of the survival of the fittest. Eager reformers should also be mindful of the eternal perversity of mankind which makes the indifferent "laissez-faire" by far preferable to enforced restraint. The truth about this is that we need stimulants to do our best work under present living conditions, and that we must exercise moderation and control our appetites and inclinations in every direction. That is what I have been doing for many years, in this way maintaining myself young in body and mind. Abstinence was not always to my liking but I find ample reward in the agreeable experiences I am now making. Just in the hope of converting some to my precepts and convictions I will recall one or two.

A short time ago I was returning to my hotel. It was a bitter cold night, the ground slippery, and no taxi to be had. Half a block behind me followed another man, evidently as anxious as myself to get under (Cont. on page 839)
An interesting study of the great inventor, contemplating the glass bulb of his famous wireless light. A full description of the invention will appear shortly in the Electrical Experimenter. This is the only profile photograph of Mr. Tesla in existence. It was taken specially for the Electrical Experimenter.
Oldest and Newest Styles in Trolleys

VERY interesting indeed from a historical point of view are the accompanying photographs, which show respectively the oldest and newest style in trolleys, in the greatest trolley town in the universe, Brooklyn, N. Y., the home of the passengers tumbled out post haste and helped the crew (he was a fine fellow) pull the car off the horse! And you paid as you entered, Oh! yes. If you didn’t pile up front and slip your jitney in the fare box, the driver (he was the whole show) bawled you out properly. When you didn’t have the change, the motorman past you an envelope containing change for your bill, and you then selected the fare and deposited it in the fare box. This wonderful mechanical masterpiece had an oil lamp inside it, so that the driver could see that you actually deposited the fare.

Electricity was a long time finding its way to trolley roads. The electric motor was developed at that time sufficiently to be adaptable for the propelling of trolley cars, but the complete details for the distribution of the current had not been fully worked out and developed to any appreciable extent. About the only thing electrical around this early traffic carrier was the “bell,” and more often than not this was simply a large clapper intended to be yanked with a pull of cord. Horse-drawn trolleys, or “horse-cars” as they used to be called in the good old days, only disappeared from the streets of New York about a year and a half ago. Up to this time horse-cars were also used on Houston Street—the greatest attraction ever to out-of-town visitors. They talked about them for weeks and weeks and weeks.

HISTORIC ELECTRIC SWITCHBOARD AND DYNAMO.

By J. Locketz.

The electric switchboard, together with the 15 kilowatt generator shown in the accompanying photograph forms a very interesting link in the history of electric light and power development. This switch-board, as well as the dynamo, date back over thirty years and were used until recently by a Western Railroad when it was still equipped with the old apparatus. The historic switch-board and dynamo have been donated to the Dunwoody Institute at Minneapolis.

The first thing that one notices on these old style switch-boards is that they are made of wood. A wooden—board was all right some years ago when 110 or 220 volts potential was considered a fairly “high” one, but nowadays when we have power developed at such tremendous voltages as 50,000 to 100,000, and even as high as 150,000 volts, there is required a better insulator than wood, such as marble.

The 15 kilowatt generator will be familiar to electricians as one of the famous old Edison machines of the bi-polar, vertical (Continued on page 808)
A “White Coal” Motor to Harness the Tides

From time immemorial men have been active in trying to evolve methods that will relieve humanity from physical toil. The worldwide campaign for increased efficiency is in a large degree dependent upon this same desire to be relieved from physical labor and there is a demand everywhere for cheap power, which can, as everyone knows, be best supplied by water power.

It is claimed by Government officials that the United States has more than 40,000,000 horse-power of undeveloped water power within its boundaries. If this is true, it represents an amount of power correspondingly to the amount of energy that would be derived from about 300,000,000 tons of coal worth about $600,000,000 a year in the boiler furnaces.

A new motor, shown in the illustrations, invented by Mr. P. J. Griffin of Boston, is designed to harness the energy of the tides and generate electricity by this means. The White Coal Motor, as it is known, is built on unique principles, being almost devoid of resistance. With this simple motor a farmer may harness the latent power of the nearest stream and generate his own electricity at very low cost. Flowing water is the only power used to generate the electricity. Mr. Griffin, the inventor, is shown on the left in the photograph.

The inventor makes use of two sets of crosses, used as arms and mounted on a concave shaft. Secured between the outer ends of said arms are a set of flaps or wings; these wings or planes are held in place on one of their vertical edges between the outer ends of said cross arms by means of a rod (or pivot, to make a circle of 360 degrees from one side of the concave shaft to the other or opposite). On account of the above radius these wings or flaps take advantage of the same currents in its reverse, identically as that of the forward serving with the same continuous motion without any change whatsoever of any part of the device.

This invention is a cross or disk, not a wheel; it becomes a motor when wholly upright shaft. With this motor wholly submerged in water the inventor claims 1,500 h.p. to 60 square feet of surface of blades with between a five and six-mile current.

As will be seen, this new tide motor is a cross or disk. It becomes a motor when wholly submerged in water the inventor claims 1,500 h.p. to 60 square feet of surface of blades with between a five and six-mile current.

Insulating rods, tongs and similar appliances have been so perfectly developed to-day that linemen often work on charged wires carrying as high as 40,000 volts with comparative safety.

A “RADIUM DETECTOR.”

A new detector of radioactivity has been evolved by a California inventor, Mr. L. M. Karsch, and it is a highly sensitive scientific apparatus, constructed on the principle of an Electroscope, by means of which it is possible to distinguish radioactive substances from others. It is claimed that the presence of radium in quantities less than 100,000,000th part of a pound can be detected with absolute certainty.

The Radium Detector consists of two insulating stands, to each of which is fastened a small “flag.” A generator, in the form of a stick of electric or hard rubber composition, 23/4 inches long, 5/8 of an inch in width, and 1/16 of an inch in thickness completes the outfit. The detector is mounted on a small sulfur compound block which forms a 3/4 of an inch cube. A small piece of aluminum sheet extends horizontally 3/4 of an inch from the cube and has a width of 3/8 an inch; it is bent into an “L” shape, the vertical side of which stands from each side of the upright aluminum 3/4 of an inch above the top of the cube. There is a thin wire stretched taut across the plate and on this wire is placed a small “indicating flag.”

Detection of the presence of Radium is accomplished by the use of two of these detectors placed on a flat surface, preferably a glass plate, at some point of height, convenient for observation. The detectors are placed six inches apart and an initial charge is imparted to each one by means of the brisk rubbing of the generator stick between a folded piece of dry wool cloth or silk. The application of the generator to the detector causes the latter to become actively charged.

After the detectors have become charged, the small flag raises and stands out in a horizontal position. The substance to be tested is placed under or near the metal part of one of the detectors, without touching it. The second detector is located about six inches away without any substance near it and it is used as a check upon the first detector. The flags of both detectors are then observed for a period of five minutes.

If the flag of the detector near which the substance or ore has been placed, drops from the horizontal position with greater rapidity than the “check up” detector, the substance is radioactive. The strength of the radioactivity can be approximately determined with this detector by noting the period of time it takes to discharge the detector. The flags will fall in about 8 or 10 minutes when a weak radioactive substance is employed, such as Uranium Nitrate, while Carnotit and pitch bled will cause the flags to fall in from two to three minutes.

By ISABEL M. LEWIS
OF THE U.S. NAVAL OBSERVATORY

Nearly everyone, with the exception of a few unusually earth-bound individuals, has felt at some time or other a strong desire to gaze at some of the beauties and wonders of the heavens thru a telescope and the one object that all of us wish to see, if, perchance, this desire is to be gratified, is Saturn, whose unusual ring system has so far as we know no counterpart in the sky.

All the planets in the solar system with the exception of the two innermost, Mercury and Venus, are attended by satellites but Saturn, alone, has in addition to a large and imposing family of nine moons, three distinct rings of great dimensions which form a total mass composed of swarms of minute particles revolving around the planet.

Why Saturn should be the only planet to possess such a system of rings has not yet been explained in an entirely satisfactory manner, depending as it does upon the manner of the origin of the entire solar system which it is now agreed could not have followed the course outlined by the Nebular Hypothesis of Laplace. The theory of the origin of the Rings of Saturn is involved in the theory of the origin of the solar system and every theory advanced to explain the manner in which the solar system came into existence must satisfactorily explain the cause of this peculiar appendage of Saturn.

There is an interesting law known as "Roche's Law," however, named from its investigator, that states that no satellite of a planet can exist intact within 2.44 times the radius of the planet. This limit is spoken of as "Roche's Limit" and applying it to the planet Saturn we find that the rings of Saturn fall within this limit. It does not necessarily follow from this that the minute particles of which the rings are composed are the shattered remains of one small satellite but rather that they are the material from which a satellite might have been formed were it not so close to the planet. Within "Roche's Limit" the mutual attraction of the various particles for each other that would tend eventually to gather them into one body is overcome by tidal forces that arise from such close proximity to the huge planet. The stress and strain of such forces is so great that no grouping of particles can take place. This explains, possibly, why the rings continue.
In Order to Understand How Tremendously Large the Saturnian System Is, Our Artist Projected upon the Rings of Saturn All of the Minor Planets, Including the Earth. It Should Be Understood That These Rings Are Not Solid, but Are Merely Composed of Small Little Moonslets (See Large Drawing on Opposite Page). It Will Be Noticed That If All the Minor Planets and Our Own Moon Were Laid Side by Side, They Would Just About Cover the Breadth of Saturn’s Rings. The Moon Is Arranged on the Opposite Side to the Outer and the Second Ring.

Comparative Sizes of the Nine Satellites of Saturn, Arranged in the Order of Their Distances Outward from the Planets (Reading from Top to Bottom). Titan is the Exact Duplicate of the Planet Mercury in Size, and Japetus is Very Nearly Equal to Our Own Moon in Size.

Fig. 1 Shows the Dimensions of the Ball and Rings of Saturn and the Orbits of the Five Inner Satellites.

members of our solar system may have had such appendages in the far distant past.

The appearance of the rings of Saturn as viewed from our planet changes periodically as a result of the revolutions of the earth and Saturn around the sun, which places them in constantly changing positions with reference to each other. The rings lie in the plane of Saturn’s equator, which is inclined twenty-seven degrees to its orbit and twenty-eight degrees to the earth’s orbit.

Since the position of the equator remains parallel to itself while the planet is moving around the sun, it may be said that half the time the earth is elevated above the plane of the rings and the remainder of the time it lies below the plane of the rings. Twice in the period of Saturn’s revolution around the sun, which occupies nearly thirty years, the earth lies directly in the plane of the rings and at this time the rings, which do not appear from view for a short time. The last disappearance of the rings of Saturn took place in the fall of 1907 and the next disappearance will occur in November, 1921. Between these two dates the southern surface of the rings remains the visible one. Half way between the two dates of disappearance the rings are tilted at their widest angle with reference to the earth and they are then seen to the best advantage. They are now becoming narrower and narrower and as the date of their disappearance approaches they will appear more and more like a line of light extending to other side of the planet’s equator. Even in the most powerful telescope the rings entirely disappear from view for a few hours at the

time the earth lies exactly in the same plane. It is at this time that the ball of Saturn may be seen in the sky.

How Jimmy Saved the Bank

By F. W. RUSSELL

As the hands of the big clock in the office of the First National Bank pointed nine, old Mr. Hutchinson past between the long rows of desks towards the door of the big burglar-proof safe. For the last ten years he had past along that same isle and at exactly the same hour. He reached the door and put his hand on the huge nickel-plated handle, by means of which the door was pulled open. The great weight was so delicately balanced that only a slight pull was neces-
sary to open it, but this time it did not yield to the usual effort; Mr. Hutchinson applied all his strength to the task, but the door did not yield an inch. What could be wrong?

Mr. Wallace, the president of the bank, had wanted an absolutely burglar-proof safe, so his brother, an Electrical Engineer, had undertaken to design one, which he claimed would foil the efforts of the most ambitions cracksmen. It had a marvelous time-lock consisting of five clocks timed to a hair. These, beginning at fifteen minutes to eight, closed five different contacts in a special motor circuit; that is, the first contact was closed at a quarter to eight, the next at exactly eight, and so on at intervals of fifteen minutes, until the last contact was closed at a quarter to nine, starting an induction motor which drew the bolts.

The current for this motor was brought in thru the top of the safe. Two holes had been made here which were comparatively small at the top and bottom but which bulged out at the center. Heavily flanged brass rods had been set in these holes and porcelain molded around them. These were protected by a thick layer of concrete which covered the safe on all sides, excepting the front. The current which operated the clock contacts, was supplied by a small storage battery kept in the safe and charged every day.

Mr. Hutchinson's first thought was that he might have been too soon, for even his

"No sir! no sir!" He raced on, getting his breath in gulps. "I went there at the usual time sir, and the door would not give. I know I was not ahead of time, for I waited nearly five minutes and tried again. I pulled with all my might, sir."

He paused and looked inquiringly at the secretary, who had sunk into one of the large leather arm chairs against the wall, and sat gazing at the floor. Suddenly he got up and looked at his watch, started to sit down again, changed his mind and be-
Mr. McGinnis looked at him reprovingly. "He keeps in touch with his home thru his son Jimmy's wireless. We will go and see him, if he goes with us.

They left the building together and hailed a passing taxi. After giving the direction, Mr. McGinnis settled back in the seat with the thought of a meeting and a worry. Mr. Hutchinson sat with clasped hands, and silently shook his head. He had not run into this business, and had done nothing so the man, even in anything, now that the safe which had always been his pet had failed them. They stooped on the way, and Mr. McGinnis explained to the Geographical and International Bank, securing a sufficient loan to carry them thru the day. The car soon cleared the town, and drove down-town, and sped along the smooth streets, until after a short ride it drew up before the white marble home of the Wallaces.

"You were opened by John, the butler, who informed them that Jimmy was at home. He was at that moment in his workshop, or in good American, his "joint." Was the gentlemens business very important? It was. Well John might venture into those dangerous regions if that was the case. Mr. McGinnis slowly showed enthusiasm for his task. There were memories still fresh in his mind of electrified doors. They led into the hall, and a rug in particular on which he had shown a surprising amount of activity. He approached the door cautiously and knocked.

"Mr. McGinnis, who is it?" came a voice from within.

"Mr. McGinnis and Mr. Hutchinson are downstairs wishing to see you now."

"I am coming down, too; busy too; tell them to come up on." Jimmy said this last standing in the open door. He was a tall slender man, but well built with a shock of brown hair, above a pleasant face. He was a typical "Bug"—always had a binding-post or a piece of wire in his pocket, and his time collecting "junk" or "making something." Mr. McGinnis and Mr. Hutchinson were standing in the room. It was a regular "joint" all right; wire on the floor, hung from the ceiling and draped along the wall, switches sailed up here and there, and tables and chairs covered with tools and apparatus. Jimmy swept two chairs clean, but his visitors remained standing.

"Our story begun paradoxically, for the first time in many years not pausing to weigh his words, "The bank is in great danger. The safe won't open and there are very important papers which have to be attended to. I want you to call your father, and ask him if there is any way to open it. You can get him, can't you?"

"What's this, you say, the safe won't open?" burst out Jimmy, looking dazedly at Mr. McGinnis.

"Yes, yes, and I want you to ask your father if he knows any way to open it I say, you can get him, can't you?"

"Sure, of course, just a minute." Jimmy dashed to his wireless table and threw in the antenna switch. In a moment the room was flooded with faces, and the door was being drownd by the high-pitched spark, as the call of his father's yacht was being tapped out rapidly. After the second trial Jimmy was answered by the Yacht's radio operator.

After a few minutes, Jimmy rose from the table with a downcast look. The two men hesitated a moment before opening his mouth. "He don't know—he's all excited. That's natural enough tho. He's coming right back," Jimmy stood for some time by the floor in a thoughtful attitude. Finally, as Mr. McGinnis started to go, he called him back. "Wait a minute, I have to come some way to open that safe; sit down and think; there is no use getting excited!"

Mr. McGinnis was far from being excited. "There's no use," he said, starting to go again. "You know how your Uncle

THE APRIL NUMBER "E.E."
The April number of the Electrical Experimenter will abound with new and refreshing articles. Among those in preparation there are the following attractive contributions:

"My Inventions."—No. 3 of a series by Namoco Tesla, the genius of the electrical scientist. This paper will describe his wonderful discovery of the "Revolving Magnetic Field"—the foremost advance in the art of mechanical motor, which has revolutionized the electrical power industry.

"What is the Injurious Travel Above the Earth or Thru It?" by De Forest, an exclusive feature article which you can't afford to miss. Mr. McGinnis is the author of a Thousand Uses. How it furnishes every conceivable want to the hotel guest—all at the push of a button. "New X-Rayology of the Bones," by Charles Battell Loomis. "How can Man Freeze to the Earth? Can he Exhale the Heat-Giving Radium?" by E. T. Bronson. "The Necessity of Phonograph—It won't annoy the neighbors." by Thomas Reed. "Putting It Over" on Fritz. Some Rare and Incurable Tricks of the war. by K. K. Sammurner. "New French and American Auditions."

A New Lightweight Commercial Radio Transmitter."

New Experimental Chemistry Questions and Answers," "Physics."

me, have you got 220 volts A. C. at the bank?"

"Oh yes," stammered Mr. McGinnis. "Yes, but what—"

Mr. McGinnis obeyed, and Mr. Hutchinson trailed out after him, not having recovered his senses as yet. The car was out in Front and the two got in. In a moment Jimmy came running down the steps of the plantation, which was apparently very heavy. The big car dashed thru the streets, narrowly missing several bewildered pedestrians and shoving passing vehicles into ditches. As the car drew up in front of the bank, Jimmy was out over the door in an instant, dragging Mr. McGinnis with him. When his father's secretary reached him, he was busily running the extension cord from a near-by lamp socket to the safe, in the mean time warding off a swarm of inquisitive bank clerks. When he had finished and had attached the two loose cord ends to two more protruding from the motor, he turned to Mr. McGinnis—"That motor is exactly in the way, isn't it?"

"You mean the one that draws the belts? Yes, yes, exactly; I remember that from your account. It's chained to me. What are you going to do?"

"Roll one of these desks over here," was all the answer they got. The order was given and half, who soon had one of the big flat tops on the required spot. By piling some large books and a file cabinet on top of this the required level was soon attained. Jimmy lifted up his bag and took something out of it.

Just then a little man in great excitement based in the corner of the clerks' eyes. he exclaimed. "So it is true. I couldn't believe it. What are you doing, James, my boy?"

"Little idea of mine, going to try to open it," said Jimmy, "don't get excited. I; may not work."

"Going to try to open it?" Mr. Wallace queried dazedly. He had just arrived and had driven to the bank at top speed.

"Ugh, ugh," said Jimmy. Then turning around, gave us a little idea of my fellows! In the scramble which followed some one accidentally pushed the right button, and the desk fell.

All eyes were turning inquiringly towards Jimmy, who stood on the desk holding a push button which was connected to a round black spot in the ceiling, and the desk fell. Suddenly, he stepped the button and bent his ear to the door of the safe; a low hum was heard on the inside and then a click, which was unmistakable.

A cheer burst from the surrounding clerks, and as the desk was rolled away, Jimmy grasped the big nickel plated handle, and swung the door wide open. But the mystery was yet to be explained and all eyes were again trained on the door.

"How did you do it, son? How did you do it?" gasped Mr. Wallace, looking with mingled wonder and pride at his young helper.

"Oh, it's nothing!" said Jimmy. "You see an induction motor has no electrical wire connection between the field and the armature. All nodded understandingly. And so I figured if I used a bigger and more powerful field, I ought to be able to spin that little field back, just line it up and you know what happened. Simple little thing, isn't it, when you come to think about it.

"I've done nothing that transformer you were longing for in that catalog the other day? How much does it cost?" asked Mr. McGinnis, as he sat down and began to fill out a check.

(DO I ELECTRICAL.

When Milli Ampere first saw Volt Her charms past all resistance. A mark was made in his heart poor Volt—

He never remembered her.

And she, tho plighted to old Watt, Could alternate affection,

So let her eye be keener, not Right in poor Volt's direction.

The current of Watt's wrath inflowed strong! He vowed Volt should not meter.

For daughter Polly Phase had long Hoped that Volt would be sweeter.

And so to Milli Ampere, he demanded. "What do you mean, Requesting she transform, and be. If possible, less bitter.

So Milli Ampere flitted not, she felt that it was wise, To regulate the rage of Watt

And with him synchronize.

The current inflowed fast. From her he did not roam.

They rectified divergent views And started a small Ohm.

J. F. Leggett, in Western Electric News.
Submersible Boat Resembles Sea Monster

The peculiar looking submersible one-man boat shown in the accompanying view has for its primary object, so its inventor, Mr. Worth R. Barringer, of Denver, Colorado, states—to provide a vessel of this character constructed so as to contain a single occupant and provided with suitable means whereby submergence of the vessel as well as its travel thru the water may be controlled by the occupant. He mentions, among other advantages, that it should prove useful and convenient for submarine observations and in the removal of submerged mines and for various other similar and analogous purposes. Also the inventor claims that his device can be used as a diving suit, and can be readily donned by the individual.

The body of the submersible diving suit is preferably made of aluminum. The front or nose portion of the body is provided with transparent panels or windows, as shown, thru which the occupant can see either to the right or left and forward. Suitable rubber or other flexible water-proof compartments are adapted to receive the lower limbs of the operator. An electric motor is arranged to operate a propeller, the motor receiving its current from a storage or other battery. But this is not all. The inventor takes time by the fore-lock and practises safety first. He also supplies a compres-air motor with a storage tank containing air under high pressure for operating it, all of which is used to drive the propeller. Suitable vents are provided for the efflux of vitiated air as well as air inlets or ventilators, which are arranged in the top wall of the body. These vents are fitted with suitable valves, such as the float-ball type, which will automatically close, due to the pressure of the water upon submergence. An electric light bulb is also arranged in the top of the body, which is supplied with current from the storage battery.

Sleeves made of rubber or other suitable flexible material are attached on the front of the body on either side to accommodate the arms. These are fitted with suitable gloves to receive the hands of the operator. To submerge, the human fish, a collapsible tank is arranged on the under side of the body. The tank is equipped at its lower end with suitable valves and hand-holds. There is also a pipe connecting the compress air tank to the upper end of the collapsible bellows tank, in which pipe line there is placed a suitable valve. When it is desired to submerge, the bellows tank is collapsed, the air being expelled from the tank thru suitable valves. This results in the displacement of the vessel, so that it will submerge. When the operator desires to rise to the surface, he withdraws his arm from one of the sleeves and opens a compress-air pipe valve from the storage tank into the collapsible bellows tank, thus expanding it and causing the vessel to rise, owing to the increased buoyancy.

Finally, the inventor mentions that it will of course be understood that the vessel may be provided with an oxygen supply tank, so as to afford an ample supply of oxygen during prolonged submergence of the vessel. If there is anything under the heavens that this inventor forgot, we have failed to perceive it in looking over his patent, but he might have conscientiously attached a 69 cent alarm clock to the rear wall of the inner compartment so as to arouse the submarine explorer from prolonged slumber, which might result disastrously in the event the "ship" became uncontrollable and started off on a long journey toward foreign shores. We presume the sailor carries sufficient tea biscuits in his box to weather the voyage, and providing he has the foresight to procure a few dozen choice tea and bouillon capsules as adapted by the United States Army for emergency rations, he should have a delightful cruise. Bon voyage!

PREDICT AERIAL MAIL SERVICE BETWEEN EUROPE AND AMERICA.

All mails between Europe and the United States eventually will be carried by airplane, according to Lord Morris, who has championed a movement before a Parliamentary committee for the establishment of a port of call for Atlantic aerial liners on the west coast of Ireland.

Already, he says, a regular daily mail service by airplane is maintained between England and France without interruption by the weather.

BRITISH TANKS CARRY THEIR OWN "CARPET."

The photograph herewith shows a giant British tank ready to go into action. This tank is fitted with a new superstructure, which comprises a rugged steel wire timber net. It is used to breach shell-holes, gulleys and trenches, in making advances over rough ground. This "carpet" is quickly unrolled when needed, and is very effective on rough ground. Of course giant caterpillar tracks or belts do not grip into the mud when the carpet is used, and thus one of the greatest drawbacks to the use of the tanks has been overcome. This photograph is one of the most remarkable taken during the war and shows British infantry reinforcements accompanied by tanks, all awaiting orders to "get into it." The smoke from the battle almost obscures the tanks and men in the background of the picture.
Experimental Physics
By JOHN M. FURIA, A. B., M. A., (Columbia University)

LESSON NINETEEN

Radio-activity—Experiment 108.

RAP a photographic plate in a piece of perfectly opaque black paper. Lay a coin on top of the paper and suspend a pinch of the mineral Uranium a little above the coin. Set this aside for a few days, after which time develop the plate. A shadow picture of the coin such as one would obtain after exposure to X-rays will appear on the plate. This is precisely the experiment that Henri Becquerel, of Paris, performed in 1896, which led him to the conclusion that Uranium is a source of rays that affect photographic plates and which have the power of penetrating opaque objects just as X-rays do. The rays are known as Becquerel Rays, after their discoverer, and the phenomenon is called Radio-activity. Shortly after Becquerel’s discovery Madame Curie, of Paris, assisted by her husband—Prof. Curie, made an investigation of all the known elements to ascertain which of them possess this same remarkable property that Uranium possesses. She found that Thorium in any of its compounds was a radio-active substance (Thorium is the chief constituent of Welsbach gas mantles). During the investigation Madame Curie noticed that Pitchblende (the crude ore from which Uranium is extracted) which consists of Uranium Oxid to a great extent, discharged her electroscope (a test for radio-activity) about four times as fast as pure Uranium does. She concluded that the radio-activity of pitchblende was due to some unknown element in it more powerfully radio-active than either Uranium or Thorium. After a tedious and difficult research she succeeded in separating a few hundredths of a gram of this hitherto unknown element from several tons of pitchblende. This new element which she named Radium proved to be a million times more radio-active than Thorium or Uranium. Radium has attracted the attention of the foremost scientists the world over.

Before proceeding with the following experiments let us note carefully the following characteristics of Radium. The Radium atom is heavier than any other atom. Radium constantly emits three distinct kinds of rays namely alpha, beta, and gamma which I shall refer to by α, β, and γ respectively. α, β, and γ-rays all affect photographic plates, discharge a charged electroscope and are deflected by magnetic fields. α and β-rays, both impart electric charges to bodies they come in contact with. In particular, the α-rays are not as penetrating as the β and γ-rays; they are deflected by a magnet in a direction opposite to the direction of deflection of β-rays and travel at about 20,000 miles per second. The β-rays are like cathode rays and they travel at from 50,000 to 180,000 miles per second. The γ-rays are not deflected by a magnet but they have greater penetrating power than either the α or β-rays. From these properties we conclude that α-rays are streams of positively charged particles (atoms of Helium); β-rays are negatively charged particles like cathode rays, i. e., electrons and γ-rays are irregular pulsés like X-rays.

Experiment 109.

The goldleaf electroscope, one of the oldest electrical measuring instruments known and which was described in the lesson on “Static Electricity,” was used merely as a detector of the presence of an electrical charge. This same instrument in a delicate form is used to measure electric currents of very small magnitudes where other instruments fail. In Fig. 98, A is a metal case (a cocoa can serves admirably; in fact an authority on the subject of radio-activity made the statement that he secured better results with a home-made cocoa can electroscope than with the fancy priced, highly polished commercial instruments). A metal rod E (about 1/32 inch in diameter) passes thru an insulating plug D, made of boron, amber or sulfur. C and F represents insulation of the same material as D, B and G are metal rods like E, bent as in the figure (hairpin with the enamel scraped off is quite satisfactory). H is a narrow strip of gold or aluminum foil about one and one-half inches long and 1/32 inch wide. (The narrower the strip the more sensitive the electroscope). To cut the aluminum or gold foil the following method has been found best. Place the foil between two sheets of thin paper. Press the edge of a razor flat against the “sandwich” and carefully saw (Continued on page 806)
Amateurs Win
Alexander Wireless Bill Is Killed
By H. Gernsback

The Alexander Wireless Bill and its amendment as reported in our last two issues has been killed. On January 15th the Merchant Marine Committee and the House of Representatives gave the Administration's movement toward Government ownership of public utilities a very definite setback. By unanimous vote it tabled the bill which was to authorize the Navy Department to take over and operate permanently all radio stations.

As our readers will remember from our January issue the bill was sponsored and urged by Secretary Daniels. Representative Bankhead made a motion to table the bill and Chairman Alexander characterised the proposed plan as "a hopeless task." He added: "In view of the sharp difference of opinion both in the Committee and in the House on this subject, it would be impossible to put the bill thru at this session."

As our readers will remember from our January issue, the original Alexander bill proposed to make all wireless stations Government owned, and the present wireless law, the act of 1912 was to be changed to such an extent that the amateurs were testing letters, which not only reached Mr. Alexander's committee but every Congressman and Senator of the United States as well. This unparalleled unity of the American amateurs had an instantaneous effect in Washington, and even before the hearing started, a number of amendments, all of which favored the amateur more or less were rushed thru, printed and distributed.

There were at least three amendments of which we have record. One of them, the last one dated December 11 was printed in full in our February issue. Before the bill was definitely killed, however, we had information which tended to show that the Government was not ready to make wireless a Government ownership affair. As far as the amateur was concerned we were not at all disturbed, for we said: "As a matter of fact as things stand (Continued on page 835)
America's Greatest War Invention

The Rogers Underground Wireless

(Special Interview to the ELECTRICAL EXPERIMENTER.)

By H. Winfield Secor

(Associate Member Institute Radio Engineers.)

An invention which has been termed the greatest American war achievement is the Rogers underground and sub-sea radio system. The Rogers system does away entirely with aerial wires, and it is only a matter of months now before all aerial wire systems the world over will be pulled down. The Rogers system has been accomplished by the new Rogers underground system, chief of which is the total elimination of the increase of the loudness of received signals, which is often as high as 5000 times the usual strength. Interference, too, is done away with almost entirely. The Rogers invention is of tremendous importance and revolutionizes our previous ideas on wireless to an extent never dreamt of before. We urge every one interested in radio to read the accompanying authoritative article which discloses the full technical data on the new system for the first time in any periodical.

The greatest invention in the field of wireless telegraphy since Marconi first placed commercial radio-communication on a firm basis by his historic experiments in Italy, and later in England, is without a shade of doubt this latest triumph of radio research—the "Underground and Sub-sea Wireless", conceived and developed to a working stage by an American scientist and inventor, James Harris Rogers. Mr. Rogers is known as a second Edison, among his town-people in Hyattsville, Maryland, where he has lived for many years, and now the whole world acclaims him.

It is Revealed Now That the Navy Department Had Been Using a Powerful Undersea Wireless During the War. The Instruments and System Were Invented by James H. Rogers, of Hyattsville, Md., and were Adopted by the Navy Department as an Invaluable Addition to the Wireless System of the Navy. The Two Lower Photos Show the Inventor, Mr. Rogers, in His Laboratory at Hyattsville.

Who is Mr. Rogers?

James Harris Rogers, practically unknown a few years ago in radio circles, except by a few select radio men who were investigating his invention for the Navy Department, has practically become overnight the center of all attractions in the field of science. Mr. Rogers is a son of the confederacy and a veteran of the great Civil War. He has followed electrical experimenting ever since and has been a strong devotee of radio telegraphy since Marconi performed his first experiments in this new branch of applied science. He is a refined, cultured southern gentleman who makes you feel at home at once; an invariable attribute of all of the truly great. Mr. Rogers was one of the first inventors of the "printing telegraph" and his full-sized working models saw actual commercial service on a circuit between Baltimore and Washington, also in New York, back in 1880. These were seen by the writer and are wonderful pieces of mechanism.

The Rogers laboratory, which comprises several large rooms, is lined on all sides with glass cabinets containing electrical apparatus which he has invented from time to time thru his studious career. A novel and original high frequency generator was another of the devices that greatly interested the writer. It employed a jet of water shunted by a large capacitor, the stream of water being connected to a high potential source of direct current. High frequency currents of any range up to the limit of audibility, or about 30,000 cycles per second, could be readily obtained with this apparatus. The writer merely cites these facts to substantiate the standing of Mr. Rogers in the scientific field. Hundreds of other electrical inventions have been made by this modest genius of the quiet little Maryland town of Hyattsville, and the principal outstanding fact of all of his work is that he can show you a working model of each of these inventions, unlike many other inventors whose ideas exist only on paper, and which often fall down miserably when actually built and tested.

In this connection it is interesting to consider for a moment that not one of the new wireless "static and interference preventers" proposed to the government radio experts during the war, proved practicable in the least.
The Rogers Undersea Wireless Opens Up an Entirely New Field to Submarines and Ship Communication. Mr. Rogers has recently stated that he has been successful in bringing to the surface to intercept radio messages, but the Rogers Instrument Co. has just announced that it has successfully transmitted a message from a U.S. Subsea Boat Submerged Off the American Coast to a Depth of 8 Feet and Picked Up Nauen, the German Station. At Depths of 21 Feet Stations with Wave Lengths over 12,000 Meters Were Easily Picked Up. Transmission to Submarines Has Also Been Accomplished.

For a decade Mr. Rogers has been studying radio subjects, and long before the United States entered the war he had experimented with the problem of underground aerial communication of this static atmospheric electricity. He disagreed with all authorities who believed that the air, and not the earth and water, was best suited for wireless communication. At first Mr. Rogers used the earth alone for sending messages to amateurs stationed near by. Using an audion bulb, he then buried a wire from his laboratory and heard Philadelphia and other stations. Further experiments were conducted at a laboratory

Official recognition of Mr. Rogers as the one and only original inventor of "Under-ground and Sub-sea Wireless Communication," was soon forthcoming, and here it is in brief. These two official letters of recognition of Mr. Rogers' wonderful and revolutionary invention represent but a

very small fraction of those he has received from radio engineers of high repute in all parts of the world, congratulating him on his masterly work. The Navy Department has just permitted information on the Rogers system to be given out, and how well they kept their secret during the World War, during which time this system has been in use by the Navy Department, may be judged by the fact that radio men everywhere are amazed at this feat. The distinguished radio savant Prof. George W. Pierce of Harvard University, congratulated Mr. Rogers heartily when he first tested and heard the new system work thru salt water, which he at first thought absolutely impossible.

Below we give the two letters of official recognition by the Navy Department of Mr. Rogers' accomplishments, which are all that we have space for.

In response to an inquiry from Clarence J. Owens, director general of the Southern Commercial Congress, Admiral Griffin, U. S. N., chief of the bureau of steam engineering, wrote under date of December 27, 1918, as follows:

In reply to your question regarding the originator of the underground radio system, you are advised that Mr. J. H. Rogers of Hyattsville, Md., was the originator of this system. There have been other claimants to methods of underground radio signaling, but none were useful, within the Navy Department's knowledge, to the extent of being a valuable asset to the general scheme of radio communication. The Rogers' receiving system marked the beginning of the use of underground aerials for receiving, to great advantage over raised aerials, and has been valuable to the Navy Department.

Rear Admiral Strother Smith, then Capt. Smith, wrote Mr. Rogers on December 7, 1917:

It is a great pleasure to me to feel that I have been instrumental in bringing the result of your work before the Navy Department and assisting somewhat in putting it into actual practise. Out of the many thousand ideas presented you can realize that a very, very small percentage are valuable and it is worth at least a year's work to get one that I feel will give lasting benefit to the service that I serve. The Navy Department is interested, Thru Dr. George H. Lamar and Senator Blair Lee the discovery and the status of the patents were brought to the attention of Secretary Daniels of the Navy. Secretary Daniels ordered inquiry into Mr. Rogers' claims, which showed that his invention worked, and requested Secretary Lane to give special consideration to pending patent applications.

Secretary Daniels then submitted the Rogers system to Rear Admiral (then Capt.) Strother Smith, who called into consultation Capt. Hooper. These officers made a thorough study of the system and found it practicable. Capt. Hooper ordered it installed at New Orleans first and since then it has been employed at Belmar, N. J.* and other stations.

To the American Radio Amateur:

WITHIN the next few months peace will be declared and the amateur will be allowed to operate his station as before. Thanks to Mr. James H. Rogers, it will not, however, be necessary for you to put up an aerial again—at least not for receiving. Elevated aerials will be a thing of the past, and well they may.

But ordinarily the amateur would not be permitted to use the underground aerial system on account of Mr. Rogers' fundamental patents. The writer, however, in conversation with Mr. Rogers, prevailed upon him to turn over the free use of his revolutionary, as well as epoch-making invention.

Mr. Rogers thru the Electrical Experimente therefor wishes to announce that he personally has no objection if amateurs use his system privately. It should be understood that the inventor only gives this permission to amateurs as such, and that this permission, of course, does not extend to firms or corporations or to individuals engaged in commercial Radio work. We wish to congratulate our readers upon this important decision of Mr. Rogers, who certainly deserves the everlasting gratitude of all American Radio Amateurs.

H. GERNBACH.

---

*At the time of writing this article the Belmar Trans-Atlantic Receiving Station is still employing the Rogers underground antenna.

Hyattsville, Md., January 13, 1919.

Dr. Nikola Tesla, New York City, N. Y.

Dear Dr. Tesla—

I have just read with great interest your article in the Electrical Experimenter. For years I have been a firm believer in the theory that far distant aerials were activated thru the medium of the Earth and not thru the ether above, and it is a source of great satisfaction that so illustrious a personage as yourself has held to the same belief. I have never met a scientist who would entertain such a proposition until I demonstrated to them results described in the enclosed paper, illustrating one of the ways I have found for utilizing the energy so clearly and forcibly described by you. I am, nevertheless, confronted by some who will not give up old theories. If you would do me the great honor of writing a few lines upon the subject the feature I would deem it a great favor.

Should you choose to be in Washington at any time I will be highly gratified to have you visit my laboratory and witness the results obtained.

Very sincerely,

(Signed) J. Harris Rogers.
ELECTRICAL EXPERIMENTER

March, 1919
789

near Bladensburg, which he called "Mount Hooper," in honor of Commander Hooper of the Navy, who rendered excellent service in adapting the invention to the needs of the Navy Department.

When Mr. Rogers first stated that messages could be received and sent from submarines when submerged it was unani mously declared to be impossible and the officials of the Bureau of Standards were not alone in this belief, as no less a personage than Marconi declared at a banquet given in his honor in Washington, that when wireless was used on submarines, "it was necessary for the submarine to come to the top in order to catch the ether waves."

To demonstrate more clearly the underwater station, Mr. Rogers constructed an underground station, wholly inclosed beneath the surface of the earth, there being no visual existence of it outside. This place in Prince Georges county was visited by some very noted men, including Dr. Abraham, the head of the French Scientific Commission, who, upon entering the cave at Mount Hooper expressed his amazement and remarked, "the Germans can't get us here." Lieutenant Paer, of the French Scientific Commission and the radio representative of France, also heard his native stations talking and expressed equal satisfaction, pleasure and amazement.

How He Conceived the Under - ground System.

The writer asked Mr. Rogers how he came to form the idea of the "Underground and Subsea Radio." He explained that from having studied the method of transmitting radio signals by means of an elevated antenna, the question constantly presented itself to his mind—"If 50 units of power are passed into the aerial, then what becomes of the equal amount of energy which passes into the ground?" He became so obsessed with this conundrum that he finally asked several prominent radio savants this question. What do you suppose the answer was?—"It is dissipated in the form of heat in the ground," they answered. But still Mr. Rogers thought they were wrong and now

he has proved it. Another early idea of his in the theoretical aspect of radio-communication was as follows, and very logical it was, too, as you will agree: He held that if the outer crust of the earth is a conductor, and the surrounding atmospheric envelope is an insulator, then how infinitely better must the former be for the transmission of any form of electric current.

To Mr. Rogers' mind it was more reasonable to suppose that the energy liberated at the base of an aerial was propagated thru the earth as well as thru the ether above, and that an elevated aerial, at great distance, would be activated by them as effectively as if the same point thru the ether above; when the waves thru the earth reached the base of the potential of the plate would be raised and lowered and the aerial would accordingly resonate the basic and original idea conceived and settled upon.

Mr. Rogers' first trial with the underground wireless to nearby radio amateurs began about seven years ago, but his theory of the reason why it must work was formulated over ten years ago. Further, he conjectured that much less power would be required to propagate a wave or current thru the earth's conducting crust, which for one thing has smaller geometrical dimensions, than to propagate it thru the insulating atmospheric envelope alone.

See Fig. 1.

The Theory of Operation.

A number of other radical ideas were entertained for several years by Mr. Rogers, and in the course of time he has found that his ideas were correct—it worked! It worked! Again how the radio experts far and wide are holding a post mortem inquest on their theories and how it all happened. To start with, Mr. Rogers stated, "special credit is due the following gentlemen, who have re-

(Continued on page 582)
self strongly upon my attention. My first thought was that I had discovered a new form of detector of Hertzian waves, of extraordinary sensitiveness, and was, naturally, much enthused, as any young investigator would have been under similar circumstances. But upon closer investigation of this novel phenomena I found that when the door of the closet was closed, or almost closed, the effect of the spark upon the gas burner ceased! This proved conclusively that I was dealing with sound waves coming upon a sensitive flame and not with electrical waves.

The delusion lasted, however, long enough to force upon my mind the conviction that heated gas molecules were sensitive to high frequency electrical operations, and I determined to investigate further at my first opportunity and actually discover evidence to substantiate my theory. I was unable to do this until the fall of 1902 or '03 when I returned to my gas mantel experiment. I first attempted to investigate the new detector phenomena by using two needles of steel, or platinum, placed close together in the incandescent Welsbach mantel. These needles were connected to a dry battery and telephone receiver. I was, however, unable to obtain any appreciable current between the two electrodes in the mantel. I then investigated the flame of a Bunsen burner and soon found a point in the outside envelope of the flame where an appreciable current did pass between the two electrodes, making a soft fluttering sound in the telephone receiver. (See Fig. 1, Patent No. 824,638, issued in 1906.) Then, connecting one electrode to an antenna and the other to the earth, I heard for the first time signals in the telephone receiver; signals which represented clearly the sound of the transmitting spark. Here at last was actually demonstrated my earnest belief in the existence of this new detector principle. My next step was to enrich the gas flame by putting a lump of potassium or sodium salt in the flame directly below the two platinum electrodes. This increased ionization caused increased flow of battery current, and a corresponding increase in sensitiveness of the new detector. I did considerable work then with various types of Bunsen burner arrangements for permanently enriching the gas flame, etc., and set up a laboratory type of flame detector which was actually used in 1903 for receiving signals from ships down the Harbor of New York.

The inconvenience of supplying a source of gas for the new detector was, of course, obvious, and I sought for other means of obtaining the necessary heated gas and heated electrodes. The electric arc first suggested itself. I anticipated that while this arc would be a detector, it would be exceedingly irregular and noisy in the telephone receiver. This was found to be the fact. The battery fed the arc thru the primary of the transformer, in the secondary of which was connected the telephone receiver, and, although at times the looked for response to electric waves was thus obtained, the noise in the telephone receiver from the arc was so deafening that the idea was abandoned.

The next plan which suggested itself was to use incandescent filaments in an enclosed chamber. This arrangement as well as the gas detector, was illustrated in my patent No. 979,275, which bears the first date of November 4, 1904. This patent application was actually awarded a Patent No. 979,275, April 14, 1908.

Here We Find the "Third Electrode" Placed Inside the Bulb, Where it Logically Belonged, as Dr. de Forest Points Out. Fig. 4 Shows the First Use of the "Stopping" Condenser.

(Continued on page 817)
O

NE of the most powerful wireless stations yet designed is that now nearing completion at Lyons, France, and we are indebted for the following description of this remarkable and extremely high power station and the very latest advances in radio engineering, to Dr. Lee de Forest, the well-known American radio engineer and physicist who has recently returned from a trip thru Europe. Dr. de Forest stated that apparently no expense was being spared in the design and construction of this new famous Lyons station, and that the engineers were apparently having carte blanche, for there seems to be no limit to the apparatus installed, and in contemplation for installation at this powerful station.

A glance at the map shows that Lyons lies southeast of Paris, and about half way between Paris and Marseilles. This station has been, and is at the present time, handling all of the official Government radio traffic to the United States, communicating principally with the powerful new naval radio station at Annapolis near Washington, D. C. The Lyons station is in daily communication, and has been in connection with various parts of the Continent, as well as Africa, different countries of Asia, and many other far-flung places in all parts of the globe.

At first this may sound somewhat exaggerated, but when the great capacity of this radio station and the extremely efficient apparatus is considered, it will seem all the more reasonable and possible. To begin with, the Lyons station has a very large aerial, comprising twenty strands of phosphor-bronze cable stretching away over a distance of 2,400 feet and supported on eight steel masts, each of which rises to a height of 650 feet. The masts are placed about 800 feet apart. It is interesting to note in this connection as Dr. de Forest pointed out, that the engineers responsible for the design of this station have found that contrary to the generally accepted idea concerning the effective effect of inverted L aerials of this type, that where great distances and long waves are concerned, the correct and efficient use of transmission in any certain direction about the antenna does not differ appreciably. The general direction of the present antenna is north and south, but the plan shown in the plan view of the station indicates, the free end of the huge antenna pointing toward the south.

The aerial conductors at the station end are fan-tailed together as are also and large twisted cable forming the lead-in, leads down thru a copper on top of the building, underneath which there is a large and very often circular, antenna from which lead separate connecting aerial wires to the various transmitting apparatus, several distinct types of which are installed in this station.

The lay-out of the station buildings has been planned, and the larger building, containing all of the long distance radio transmitting equipment, is in the form of a cross. West of the large building there are two small structures, a small one containing a 3-K.W. high-frequency generator of the beltender (French) type, having a speed of 6000 r.p.m. operating at an antenna frequency of 80,000 cycles. The building next to this houses a 150-K.W. arc generator of the Elwell type, and this transmitting set has an antenna running to the central aerial switch in the main station building. This particular set is of great interest to Americans, as it is the one which has been used in transmitting all of the official Government messages to the United States. It has been operated right along with a United States naval radio crew, and has been very busy night and day. The powerful arc-oscillation generator has been in use continuously, and has often required twenty-four hours of operation, only shutting down the arc periodically for renewing the electrodes.

The following description of the main station transmitting equipment, which is being installed in duplicate, is given in the order of its installation, the first apparatus described being the older.

In the long northern wing of the station of the main building there are installed two 150-K.W. spark sets. These are somewhat similar in design to the well-known General Electric-Alexander design, rated at 150 K.W., and the other set being of the Beltender (French) design, rated at 150 K.W. and twenty-four hours of operation. They are tuned and adjusted to operate at an antenna frequency of 20,000 cycles. By means of the cleverly arranged automatic switch-gear, either of these sets can be connected up to the antenna. Also, when necessary, two such sets may be connected in parallel to the antenna for extra long range.
Experiments With Ultra-Violet Light

By J. C. MORRIS, Jr.

ALTHO the majority of experimenters are interested in the subject of X-Rays, little attention has been given to the study of the ultra-violet rays. These rays have been extensively studied by Finsen and other investigators and were found to have a wave length of about 3600 A. This is far too short a wave to be seen by the human eye, but their production is usually accompanied by manifestations of visible light.

All of the apparatus required to produce these rays is extremely simple and is to be found in nearly every experimenter's workshop. Figure 1 shows how the apparatus is connected: C is an induction coil giving a spark 1 inch or more in length; L is a Leyden jar of other form of high voltage condenser; H is a coil consisting of 10 or more turns of heavy wire (a good wireless helix will do very well) and G is the generator of the ultra-violet rays. It consists of a spark gap whose terminals are composed of iron or steel nails. A convenient form of generator may be made out of a short length of cardboard tubing, thru which the nails are driven. A gap of 1/8 inch must be left between the nails. A small opening must be cut in the tube in the rays to pass thru. A quartz (not glass) window may be placed in the opening, if desired. See photograph. A small spark gap may be placed at N, if desired.

The following are some simple experiments with the ultra-violet rays.

Experiment No. 1.—Secure it possible a piece of willemite (which is a natural silicate of zinc). When the willemite is exposed to the ultra-violet rays it will fluoresce with a pale greenish color. This is a test for zinc.

Several other substances besides willemite will fluoresce when exposed to these rays, among these are sodium silicate, fluorescence, acetylum, sulfate of quinin, also platinum—barium-cyanid screens, such as are used for X-Ray purposes.

Experiment No. 2.—One of the most peculiar properties of the ultra-violet rays is their ability to ionize air; that is, to make air a partial conductor of electricity. The following three experiments demonstrate this property of these rays.

Make two disks of metal about 5 inches in diameter. Place one of these on top of an electroscope. Suspend the other about 1/2 inch above the electroscope. Now charge the electroscope with positive or negative electricity. Focus the ultra-violet rays between the plates. The electroscope will soon be discharged, due to the ionizing (rendering conductive) effects of these rays. This experiment is given for producing these rays in quantity is illustrated and described hereafter.

Experiment No. 3.—Start a small induction coil and separate the secondary terminals just beyond the sparking distance; focus the ultra-violet rays on the spark gap. The spark will now jump the gap, due to the ionizing effects of these rays.

Experiment No. 4.—Take two small metal sheets and separate them a short distance apart. Connect these plates in series with a powerful high voltage battery and a very sensitive galvanometer or telephone receiver. No current now flows, due to the resistance of the air gap. Focus the rays between the plates and a minute current will now flow, due to the ionizing effects of these rays.

Experiment No. 5.—Start the generator of the ultra-violet rays. Place a piece of glass in front of the opening. Examine a piece of willemite. It does not fluoresce. Substitute a piece of quartz or of ice in the place of the glass. The piece of willemite will now fluoresce. Substitute glass that is opaque to these rays, while quartz and ice are transparent to them.

Experiment No. 6.—There are certain substances which are able to transform the short ultra-violet rays into visible rays of light. A Geissler tube is a generator of these rays and may be used to show the fluorescence of certain substances. Make a fairly dilute solution of sulfate of quinin, and add a few drops of sulfuric acid. Partially immerse a Geissler tube into the solution and connect with an induction coil or preferably to the positive pole of a static machine. While the tube is being operated the solution will appear to be light blue in color.

Other substances besides quinin will fluoresce. Some of these are acetic acid, fluorescein, and hydroquinon, such as used in photography.

These are only a few of the many interesting experiments which can be performed with these rays. The photograph is a picture of the author's apparatus for generating these rays. This sketch of the ultra-violet rays is exceedingly interesting and will amply repay the time spent in making the apparatus. It represents an uncommon field for experiment and one that holds much promise for the future of science.

WORKSHOP ACCIDENTS.

It is well to know what steps should be taken in the case of minor accidents that may happen tohandicraftsmen and experimenters in the prosecution of their hobbies. These are mostly in the nature of cuts, scalds, and bruises. It is a good plan to keep a lump of alum handy to stop the bleeding in the case of small cuts. Toil alum, sold by druggists, is the best, and is preferably used by those who shave themselves.

A simple clean-cut wound should be cleansed in cold water under the tap, which generally stops the bleeding at the same time, after which the sides should be brought together carefully and supported with strips of sticking plaster held in position by a bandage.

Wounds inflicted by rusty nails and other pieces of metal often lead to serious inflammation or blood-poisoning. These ill effects may be prevented by the following very simple remedy. Place a little brown sugar on a fire shovel and heat until it smokes, holding the wound in place for several minutes. A few scraps of clean woollen rag will answer the same purpose, but sugar is best. Peroxid of hydrogen and iodin tincture are reliable solutions for treating wounds that involve abrasions.

Some boric acid ointment should always be kept available in case of large cuts or wounds, resulting in a raw surface, or a strong solution of washing soda may be used. Severe burns, and in particular those caused by splashes of molten metal, are best treated with raw linseed oil poured over the burn and covered with a pad of lint.

Hook-up of Spark Coil, Condenser, Induc- tance and Spark Gap for Producing Powerful Ultra-Violet Rays.—Fig. 1.

Small splinters of steel or wood are often run into the flesh and cannot be removed with the fingers alone. In the absence of a pair of fine pointed tweezers an ordinary sewing needle may be employed. Heat the end of the needle, or dip it in peroxid of hydrogen, iodin, or carboic acid and water, to kill any germs on it before touching open cuts. Slip the eye of the needle over the protruding end of the splinter, give it a twist to make it grip, and then raise the needle when the splinter will come out as well in most cases.

Wood Finishing for the Amateur

By ARNO A. KLUGE

WHEN the experimenter is con- 
scious of the presence of apparatus, 
whether it be an instrument cabinet 
or of Tom Reed’s famous 
clocks, he is confronted with 
the problem of choosing the wood to give it, 
if such there be. We often find that 
this last process is neglected to a degree where it 
seriously affects the appearance of the instrument, 
and as “looks is everything” to the uninitiated, 
we should give the matter a little more time and study, 
for a number of general processes used in finishing 
a piece of wood, namely: Sandpapering, Stain- 
ing, Filling, Starching, Varnishing, Rubbing, and Polishing, in the order 
in which they occur. Each of these 
will be treated separately, also any 
subdivisions which may come under 
them; but we should bear in mind 
that it is not always necessary to use 
all of them, and so the finisher 
should select that which suits the 
piece to use before starting any piece 
of work. Also, of all the material 
required, he should have on hand so that 
the work may proceed expeditiously 
and without waste of time.

The first operation, that of sand- 
papering, is to give the wood an 
absolutely smooth surface and prepare it 
for the filling. It is assumed, of course, 
that the wood has already 
been planed reasonably smooth, so 
that No. 0 sandpaper is about right for 
the job. A sandpaper block about 
four inches square and one inch thick 
should be prepared, taking care 
that one of the four-inch surfaces is 
perfectly flat, with no high corners. The 
piece of sandpaper is placed under- 
neath the block, the surplus sides 
turned up, and the sandpapering done 
ACROSS the grain. Never sand- 
paper with the grain, as this produces 
tiny grooves on the surface, especially 
with soft woods.

One other precaution should be 
noted. Be careful when sandpapering close to the edges, they will 
be rounded off if you bear down too 
hard. If desired, a piece of scrap 
wood whose surface is flush with the 
work may be laid up against the 
edge, so that the sandpaper will pass over 
to this piece when it reaches the edge 
of the work. After these operations are 
completed, the filling is in order, and it should 
be done thoroughly, to remove every 
particle of dirt from the surface.

We are next ready for staining the 
wood, if desiring to change its color in any way. Remember, however, that staining is only 
resorted to when we do not wish to finish 
it in its natural state, but have decided 
either the exact processes he is to follow, or give it 
another in imitation of some other wood. Most hard woods are more beautiful 
in their own color than they are in a false 
dress.

There are two kinds of stains 
in common use, and both have their faults and good 
points. There are the aniline stains, in which 
the pigments are reduced to a workable 
consistency by the use of turpentine, 
namely, the different aniline dyes, 
as indicated by the name, use water in 
preparation, and hence must use water-soluble 
 pigments. The main advantage of the 
 oil stains is that they do not raise the 
 grain of the wood, and do not show the 
 laps of the brush strokes upon soft, open 
grained woods such as white pine, poplar, etc. 
Upon hard woods, however, they do not 
penetrate deep enough to be desirable, and 
water stains are commonly used for such. 

Water stains are very penetrating, and if 
properly made will bring out the grain of 
the wood very beautifully, instead of cloud- 
ing it as most oil stains do. Their 
chief fault lies in the fact that they raise 
the grain, involving additional sandpapering 
to obtain a level surface, but this is offset by 
the additional beauty of the finished 
product.

The above formula is typical of all aniline 
stains.

Antique Oak. Dissolve asphaltum in naphtha, 
making a very thin mixture, and then 
should be the antique filler.

The third step is filling the wood, if staining 
has been necessary, and by this we 
endeavor to level up the surface, and get a 
mirror-like smoothness. It is best to 
purchase fillers ready-made, and it is difficult 
to get the proper consistency. They consist of 
very fine silica stone, in a mixture of 
half linseed oil and half turpentine, 
with the proper filler added. After the filler has been 
applied, and its color begins to 
change to the finish, it is dull to 
be rubbed dry. 

After filling, shellacking is re- 
sorted to with hardwoods, in order 
to close the pores, and also to use 
hard pressure, so as not to cut thru the 
coat of shellac. With new 
sandpaper it is best to rub two pieces 
together several times to remove the 
danger of scratching.

When applying varnishes a brush 
suited to the size of the work should 
be used, and the operation should be 
performed in a room temperature 
of at least 70°, to insure free flowing. 

Altho it is impossible to tell just how 
varnish successfully, practise being 
the only way to learn, a few simple rules may be given. Apply the 
varnish with the flat of the brush, 
along the grain; then rub it out crossways 
to get an even application; finally 
finish it off with the grain. Care 
should be taken not to apply too much 
at one time, but at the same time not to put too much on. This is another matter where 
practise is the only answer.

After one coat of varnish has been 
applied and is thoroughly dry, the surface 
is rubbed smooth, using ground pumice stone and 
and a pad of roughing felt, until the fibers of 
are the best, as there is less danger of scratching thru 
the varnish. One should always rub with 
the grain and not bear down too hard at 
the beginning or end of the strokes. Some 
lime oil should be at hand as rubbing oil, 
the felt being dipped into the oil and then into 
the pumice stone. As the fibers 
are thus adhering to the felt, cleaning 
off should be done at once, using soft 
cotton cloth. This is necessary, as any 
remaining coarse fibers should not be rubbed until 
two or more coats of varnish have been 
applied, waiting each time until the 
previous coat is dry. This is necessary, or the 
fibers will come up above the surface, thru 
the varnish.

Having rubbed the surface perfectly 
smooth we may now give it a high polish, 
or we may leave it with a “dead” finish. If 
polishing is elected we may proceed in 

(Continued on page 810)
SILICON is the central element in the mineral world, like carbon is in the animal and vegetable kingdom. Unlike carbon, silicon never occurs in the free state. Next to oxygen, it is the most abundant element. Oxygen is estimated to make up nearly half of the solid crust of the earth, and silicon to constitute about a third more. Its occurrence is chiefly in combination with oxygen in quartz and silicon dioxide (SiO₂). This non-metallic oxide is often further united with some metallic oxide, such as aluminum oxide (Al₂O₃) to form a silicate. It is, further, the chief constituent of nearly all rocks, and consequently, also of the soils which have resulted from the decomposition of rocks. It is also found in ashes of many plants, having assisted to make up their mineral structure. Despite the fact that this element is so widely distributed, the element itself has been, until recently, separated from its compounds only with such great difficulty that it was only a curiosity. By the present methods of reduction it is no longer difficult.

**History.**

Amorphous silicon was first separated and isolated in 1810 by Berzelius in an impure form. Later, in 1823, he obtained the pure element, by fusing together iron, carbon, and silica (Silicon Dioxide SiO₂). Deville prepared the crystalline variety in 1854, and in 1864 first reduced it by magnesium.

**Occurrence.**

As previously stated, the element does not occur in the free state. Its affinity for oxygen is so great at a high temperature that in early ages, when the earth was a molten mass, the silicon all combined with oxygen to form silicon dioxide (Silica SiO₂), this later uniting with metallic oxides to form silicates.

**Preparation.**

Amorphous Silicon is best prepared by mixing powdered coal with a mixture of powdered and well-dried white sand (SiO₂) and magnesium. This mixture is placed in a test tube and heated with a Bunsen flame. The reaction soon begins with a glowing which quickly extends through the entire mixture.

\[ \text{SiO}_2 + 2 \text{Mg} \rightarrow \text{Si} + 2 \text{MgO} \]

The cooled, hardened product is powdered and then washed with dilute Hydrochloric Acid to remove the magnesium oxide. The product thus obtained is an amorphous, brown powder, which, when heated in air, ignites and burns with the formation of the dioxid SiO₂.

Silicon is insoluble in water and acids, except hydrofluoric, which dissolves it readily.

The crystalline variety is prepared by fusing sodium silico-fluoride with aluminum, or zinc and sodium:

\[ \text{Na}_3 \text{SiF}_6 + 4 \text{Na} \rightarrow 4 \text{NaF} + \text{Si} \]

The liberated silicon dissolves in the fused metal and on cooling crystallizes. The crystals are separated from the mass by treating successively with hydrochloric, boiling nitric, and hydrofluoric acids. Crystalized silicon is also prepared in an electric resistance furnace from pure silica sand and finely pulverized foundry coke.

\[ \text{SiO}_2 + 2 \text{C} \rightarrow \text{Si} + 2 \text{CO} \]

**Properties.**

The silicon of the silico-fluoric process is in the form of hard, brittle crystals, possessing a degree of hardness, sufficient to scratch glass. They withstand white heat without igniting and resist the action of all acids except a mixture of hydrofluoric and nitric, which, when hot, dissolves them slowly.

The silicon product of the electric furnace is in the form of crystalline masses, having a lustre of a dark silver luster. It is quite brittle and melts at 1420°C.

**Fig. 161. Illustrating Various Optical Properties of Glass.**

**Glass.**

What a common substance! Among the many necessities of daily life, few manufactured articles are more important than glass. The importance of this substance will be brought home forcibly when we only mention the sciences of Chemistry and Physics and all branches utilizing the microscope and telescope (see Fig. 161) would probably never have been advanced to their present elevation. Bacteriology and its allied studies would have been unexplored, and as a result the lives of many who have been cured by microscopic examinations and subsequent proper treatment would have been sacrificed. Aside from the fact that it is an everyday necessity, being employed among other equally important uses, as a container for the milk which is delivered in the morning, the glasses used for drinking purposes; in rural districts as chimneys for lamps; and in large cities and dwellings for electric lamp and gas lighting. It would tax the reader too much to even for a moment try to imagine what kind of an existence we would have without our glass windows. It would mean that we would have no use for clocks, as our time would be controlled solely by the sun and moon; which is great if you can such a superstructure as the Woolworth Building, as well as many others, practically a city in itself without windows.

It is true that there may be other substances, but it is hard to conceive of anything which would compare with glass.

What is this substance which we could hardly do without? Generally speaking, it is an amorphous mixture of the silicates of calcium or lead with those of an alkali carbonates or silicates, obtained by fusing sand (Silicon Dioxide), lime or lead oxide with sodium or potassium carbonate. The cheaper grade of glass contains instead of the alkali carbonates a mixture of one of the sulfates and coal dust. Thus the sulfates are reduced to sulfids, which form silicates with the sand. Upon the composition depends the degree of fusibility, hardness and refractive powers of the glass. Thus we must distinguish between the various kinds.

**Fig. 159. The Ingredients Used in Making Glass Are Placed in Refractory Fire Clay Pots. The Glass Is Melted at a Great Heat in a Furnace.**

**Lime (Plate) Glass:** This grade is much cheaper, harder and less fusible than "lead" glass. It is either a soda or potash-lime glass, which is readily fusible, is the common sort, such as is used where cheapness is desirable, such as is used for window glass, plate glass, bottles, etc. The potash-glass, also known as Bohemian and Crown glass, is a silicate of lime and potassium. This kind fuses only at a high temperature, and is harder, and withstands the action of water and acids better than soda-glass. For this reason it is used extensively for the manufacture of chemical glassware, such as test tubes, for highly temperatures without fusing. Potash glass is used for Leyden jars.

**Lead (Flint or Crystal) Glass:** Litharge (PbO) or red lead replaces the calcium oxide of lime glass. This kind is used for cut-ware, optical glass, such as lenses and prisms, being heavy, possessing great luster and brilliancy.

Replacement of a portion of the lead oxide by thallium oxide or boron tri-oxide, causes the refractive property of the glass to be increased considerably. Such a glass is called "strass" and finds use in the manufacture of imitation gems.

The varied colors of glass are obtained by the addition of various metallic oxides or salts. Blue glass is made with cobaltic oxide or copper oxide; Violette glass, by using manganese dioxide; Red by metallic copper

SECOND PRIZE, $2.00

SIMPLE RECTIFIER MADE FROM POLARIZED RINGER.

The materials required are: a low-resistance polarized telephone bell, two pair of binding posts, preferably rubber-covered, about 3" of 1/8" x 1/16" brass or copper strip, and a plain wooden base, 4" x 3", and two silver dimes.

Remove the gongs from the bell and mount it on the base by means of two oblong blocks of wood, to the ends of which are screwed the attachment lugs on the bell; the blocks in turn being screwed to the base. Bend up 1" of each brass strip. To the upper portion solder half of a dime, previously filed to a smooth surface. Solder the other two halves of the dimes onto opposite sides of the hammer; see sketch for arrangement of parts. These two strips must be held down to the base by a pair of small screws. The two pair of binding posts should be placed at opposite ends of the base. Connect as in wiring diagram.

Simple Rectifier Constructed From Polarized Ringer.

This rectifier will only handle currents from 1 to 9 amperes without dangerously overheating and operates best on 25 cycle frequency. Connect the terminals leading from the coils directly to the 110 volt A. C. current; direct current at about 50 volts D. C. will be obtained at the other terminals, due to auto-transformer action and drop due to resistance of contacts. Lubricate the armature pivots.

Contributed by GEORGE LUNGE.

FIRST PRIZE, $3.00

HOW TO MAKE A TABLE LAMP FROM SHEET METAL.

Cut four pieces of sheet iron, brass or copper, as per Fig. 1, solder together and then cut one piece as in Fig. 3, and fasten to this. Then cut one piece like figure 2, and bend as on dotted lines, making a stand three inches square and twelve inches high. Put this thru the opening in the completed base until it strikes bottom, then solder securely; cut a hole for the cord about one inch from the top of the base.

Next cut one piece (Fig. 6) for socket and solder socket base securely to this, then wire up, putting wire thru base and soldering top on. For the shade holder cut four pieces of 1/4" iron or brass wire and solder as in Fig. 4. For the shade cut four pieces (Fig. 5) and solder; then fasten to holder. You can glue a piece of felt on the bottom of lamp. A ten-cent can of Mission Green enamel will make an attractive color for the lamp, if it is to be used in the deg.

It is a Simple Job to Cut Out the Parts for Making the Table Lamp Here Shown. Copper or Brass Gives a Fine Finish.

The shade may be made quite artistic at small expense by cutting out the side of the shade in some such pattern as shown. These are backed up by pieces of ground glass cut after the pattern of Fig. 5, or figured glass may be purchased reasonably at any fixture shop. If made of brass the lamp may be polished and lacquered or given an oxidized copper finish. Such a lamp will prove very useful in the camp and bungalow.

Contributed by M. F. HOLMES.

THIRD PRIZE, $1.00

HOW TO MAKE A COMBINATION VOLT AND AMMETER.

A combination meter can be made from a burned out or otherwise damaged winding of a volt or ammeter of the permanent-magnet pocket type.

Remove the old winding and rewind with No. 20 silk covered or enameled magnet wire, fastening the negative end to the shell or negative terminal, and the other end to the positive terminal. This is the weak current reading, such as for old cells, coils, etc.

The volt reading is obtained by connecting a resistance (R) of varied size at J, and terminal V, which is tested by a dry cell reading approximately 1½ volts.

The amperes are now read by connecting a piece of No. 22 or 24 copper wire (A.W.) in shunt with the coil at J and a suitable switch, SW, to the case. The proper length may be found by testing with a cell of known amperage.

Contributed by L. W. CAMERON.

This department will award the following monthly prizes: First Prize, $3.00; Second Prize, $2.00; Third Prize, $1.00. The purpose of this department is to stimulate experimenters and for the most useful, practical and original idea submitted to the Editors of this department, a monthly prize of prizes will be awarded. For the best idea a prize of $3.00 is awarded; for the second article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings. Use only one side of sheet.
HOMEMADE PERISCOPE FOR READING TEMPERATURES AND OIL GAUGES.

The submarine commander has found the periscope invaluable for readily locating enemy vessels and obtaining his bearings under war-time conditions, and any electrician or engine room attendant, who has once used one of these home-made periscopes for reading meters, oil gauges or thermometers in inaccessible places, will never be without one. To make one of these periscopes, procure a piece of round or square metal tubing about two inches across. The tube may be of any length desired. Two small mirrors of suitable size are procured at a ten-cent store, and these are placed at an angle of 45 degrees, one at the bottom of the tube and the other at the top of the tube, in the manner shown. The image of the scale is reflected in the top mirror, thence down the tube onto the face of the lower mirror, and then out thru the opening in the tube to the eye. In some cases, these meter-reading periscopes are fitted with flashlight bulb at the top and a push button and battery on the base of the tube suitably secured in place, in order that the gauge may be illuminated.

MAKING FLEXIBLE-CORD COVERS.

Cut a strip of cloth, any kind and any length, half an inch wide, fold it lengthwise as in Fig. 1, with the wrong side out if there is a wrong side, and sew a line of machine stitch down the side as shown. Don't try to sew too near the edge.

Next, run a piece of stout twine thru with a tape needle, as shown in Fig. 2. When thru, gather the upper edge of your cloth tube together, as in Fig. 3, and sew it to the piece of twine. Don't try to tie your twine, as that makes rather too large a knot to start thru easily.

Now hold the other end of the twine in one hand (or if your tube is very long, tie it to a door-knob) and with the other hand work the puckered end down inside, with a motion like pulling on a glove-finger, (Fig. 4). Once started, there is not the slightest difficulty.

Fig. 5 shows the end of the operation, with the completed tube coming thru, right side out, with the seam concealed, and with the extra flap serving to stuff the tube and make it plump and round. The conductor, composed of a dozen braided wires from your old Ford secondary, is run thru with the tape needle, and there you are. Cost per yard, exactly $0.00.

I have a particular affection for this invention because I had a dollar on it once—about the only dollar I ever did wring from Science. The stenographer was aiming to replace a broken belt-loop on her velvetcost, and was stumped to know how the tailor had got the seam inside. Recognizing my old process, I was explaining it to her, when the boss came in and bet me a dollar I couldn't do it. The girl made the tube, I ran the string, manipulated a second, and "Past" thru it went, like a rat two jumps ahead of the feline. The boss handed over his dollar, while the stenographer said something which in polite such cases will be very turbid and in a state resembling fermentation. Contributed by ARTHUR SCHALLER.

NEARLY PERFECT—WHAT 1/1000TH INCH ACCURACY MEANS.

Such is the perfection of modern machinery that 1/1000th of an inch is a large error in metal working, tho a sixty-fourth of an inch was near enough for the craftsman of the years ago. Optical glasses, like lenses and prisms can now be made with surfaces accurate to 1/50,000th of an inch without undue difficulty, and for the most exacting purposes, glass objects can be so worked that it is possible to make a flat or curved surface to an accuracy of one millionth of an inch.

But even such marvelous accuracy as this falls far short of theoretical precision. If the most perfect mirror could be magnified until the molecules became visible, it would appear anything but flat. In fact, when X-rays were discovered this form of radiation appeared not to be subject to regular reflection like a beam of light falling upon a mirror. This has since been found to be due to the fact that the most perfectly polished surface is relatively rough to the exceedingly short waves of X-rays, just as a sheet of paper is rough to ordinary light, and so reflects it diffusely. Contributed by H. J. GRAY.

PREPARATION OF PYROMORPHIC CARBON.

Pyromorphic carbon is a substance which takes fire spontaneously. It is prepared from lead tartrat. To prepare the lead tartrat mix solutions of tartaric acid and lead acetate. Lead tartrat is precipitated. This is filtered, washed and dried in the air. Next an amouple is prepared by drawing out a test tube. (See diagram.) The tartrat is now put in the amouple and heated until no more white fumes are given off. It is then sealed at the constriction before cooling. After it is thoroly cooled and if the tip is broken off the substance when sprinkled out will burst into flame before reaching the floor.

On heating, lead tartrat decomposes, leaving lead and carbon. These are in such a finely divided state that they absorb oxygen—thereby bursting into flame.

LIGHTING A BUNSEN BURNER WITHOUT MATCHES: If a crystal of potassium chlorat is rubbed on the side of a safety match box, tiny sparks of flame will result. This is due to the combustion of the phosphorous on the box with the oxygen of the potassium chlorat. Contributed by JOE BRENNAN.

ANOTHER STORM GLASS OR BAROSCOPE.

Potassium nitrat: . . . . . . Gr. 30
Ammonium chlorid . . . . Gr. 30
Absolute alcohol . . . . Fl. Dr. 6
Alcohol . . . . . . . Fl. Dr. 6

Put the mixture into a bottle 18 inches in length and 1/4 inch in diameter, and cover the mouth with a piece of perforated plaster.

If the weather is to be fair the insoluble matter will settle at the bottom of the tube, while the liquid remains pellucid; but previous to a change for rain, the compound will gradually rise, the fluid remaining transparent. Twenty-four hours before a storm or very high wind the substance will be partly on the surface of the liquid, apparently in the form of a leaf; the fluid in

Contributed by S. GERNSBACH.
of accomplishing this object. Each one of the cells is closed and a vent pipe is connected to its interior, which is arranged to discharge the fluid, and to the outside of the box. An arrangement of inlets and outlets valves and an air pump regulates the discharge of the gases, acid, electrolytes, etc., that may escape from the cells by accident. Also a means of air circulation is provided around and between the cells for regulating the battery temperature.

**Electrolytic Process** (1,282,262; issued to Matthew M. Merritt)

A new improvement in the manufacture of copper or other metallic sheets by electro-deposition on a rotating cathode. By proper control of the proportion of the surface of the cathode which is immersed, to the speed at which the cathode is rotated, the formation of rough deposits on the deposited sheet caused by liberated hydrogen may be reduced to a minimum. Also the burning of the deposits by the use of a high current is also eliminated, while maintaining that rate of deposit which is satisfactory from a high current density. Also the current is automatically balanced by the formation of various oxides, which results from a high amperage during the deposit, may be avoided by the use of an oily or greasy coating over the surface of the mandrel, which is preferably treated with mercury.

**Annaling Metal Wire by Electricity** (1,285,887; issued to Herbert Alexander, Wyndham T. Vint and Arthur Inberry)

Annaling and tempering of traveling steel and other metal wire has, previously been accomplished by its being made to form a part of an electric circuit, the ohmic resistance of the wire with the requisite amount of current flowing automatically producing the desired heat. This invention improves on this process in that it consists of a means for the gradual heating of the wire when first entering the apparatus or after emerging from a cooling bath thereunto, including a mechanism for holding the coils in place. A periodicity of over 25 cycles per second is an advantage in overcoming the tendency to the production of non-electrolytic phenomena which may occur.

**Collapsible Wireless Telegraph Pole** (1,285,940; issued to Leon Chodkowski)

Atta-Boy, Leon. Why didn’t you think of this before the war, you silly fool, I wish I had! That’s thanks to Mr. Roger’s underground radio. A wire-less telegraph pole of the collapsible type for elevating the wireless antenna consists of a semi and inflatable bag adapted for arrangement in pole form, which is inflated and carrying wires near the top. The device is so made as to be readily filled with gas and emptied as desired. A means of carrying the gas in tanks with the signal corp section may be provided for the filling of the bag, or competent air may be used.

**Means for Recording Sounds** (No. 1,286,259, issued to Thomas A. Edison)

This invention relates to an improved method of recording sounds. Its object is the making of small discs for talking pictures. Where only a single horn is used to catch the sound waves a very poor impression is received on the record and many of the sound waves are not caught at all. In this invention the sound waves are collected at a plurality of points which are so separated as to extend over the field of action. It also intensifies the impulses before they reach the recording device. A number of microphones and the receivers are connected in series with the battery and the primaries of the induction coils, corresponding in number to the receivers, are also in series with each other and the microphone upwardly extending arms from the base. The arms are constructed by means of pivots so as to enable the body to swing in any direction of flight the plane might assume. Any shift of this spherical body tends to raise or lower a disc which floats on the surface of the liquid and this shifting disc automatically adjusts the planes and keeps the machine in equilibrium.

**Wireless Apparatus and Method Therefor** (1,279,850; issued to William Dubiler)

The apparatus consists of a simple, light weight electromagnetic vibrator intended to produce oscillations. As a closed circuit condition exists at starting the oscillations, a high primary potential is not necessary, and therefore a direct current source of energy of low voltage is sufficient to operate the apparatus. It operates most efficiently when the period of vibration of the spring of the vibrator is in a selected ratio to the natural frequency of the oscillating circuit; that is to say, when such period of vibration is either equal to or a harmonic of the natural frequency of the oscillating circuit.

**Target Apparatus** (1,286,215; issued to Clarence H. Brainard)

Each plunger is so set in the target that it is immediately absorbers all the kinetic energy of the bullet on impact and then drops the bullet into a receptacle. At the same time the movement of the plunger actuates an indicator by closing a switch arranged in the path of the bullet, and electrically connected in the circuit with one or more annunciators, properly numerated.

**Process and Apparatus for Inducing and Stimulating Rainfall** (1,284,982; issued to John C. Ballestine)

An electric conductor is used to form a path for the flow of energy between earth and clouds. The lower end of such conductor being connected to the earth and the upper end having a terminal of electrically conductive material. To secure effective connection between earth and clouds it is necessary to have the upper terminal consisting of a great number of fine metallic points. For practical purposes the upper terminal consists of a mat or fabric sheet of considerable surface, with a great multiplicity of electrically conductive points, and its area is two to ten square yards.
Our Amateur Laboratory Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of apparatus unaccompanied by that of the owner. Dark photos preferred to light-toned ones. We pay $3.00 prize each month for the best photo. Address the Editor, "With the Amateurs" Dept.

"Amateur Electrical Laboratory" Contest

THIS MONTH'S $3.00 PRIZE WINNER — E. J. J. Gobrecht

The accompanying photograph shows the laboratory of this month's prize winner, E. J. J. Gobrecht, who has certainly one of the most interesting that we have had submitted for some time. Everything is systematic, and there is sufficient space to have a place for everything and everything in its place. At the extreme right may be seen an elaborate switchboard containing several knife switches as well as a specially made heavy current rheostat, current meter, switchboard lamp, testing lamps, telephone transmitter, etc. Storage batteries can be charged from this switchboard when desired, and several of them may be seen on the laboratory bench in the background. The table in the foreground contains an electrolytic interrupter operating a spark coil, a pair of home-made Leyden jars and a small Oudin high frequency coil having a primary wound with copper ribbon. Several small dynamos and miscellaneous tuning coils, loose couplers and rheostats are to be seen about the laboratory showing that the owner has been actively interested in the theoretical and practical study of electricity and wireless. The usual collection of "miscellaneous" comprises telephone parts, boxes of screws and nails, wet battery elements, chemicals, etc. A goodly assortment of tools are on hand for the construction of the various apparatus which the author happens to be interested in. Note the beautiful model of a monoplane suspended in front of the central window of the laboratory, also the partly constructed model airplane fuselage on the floor just under the center table. Also do not miss the large sketch of Dr. Nikola Tesla on the rear wall, presumably enlarged and sketched from the supplement given with the "Electrical Experimenter" several years ago. There is a photopath in the laboratory to stimulate ideas at odd moments when the owner's "think tank" goes dry. This is a good specimen of what the average American boy can do in making up an attractive and useful workshop in which to try out his ideas and supplement his theoretical studies with the actual application of the principles involved.—E. J. J. Gobrecht, Hanover, Pa.

HONORABLE MENTION (1 Year's Subscription to the "ELECTRICAL EXPERIMENTER") — WM. H. MOORE

I give herewith contents of my laboratory. Among the usual requisites of such a laboratory there are: 2 K.W. high frequency sentit. 2 Mignon Audion cabinets, 5,000 meter coupler, together with smaller couplers, phones, storage battery and condensers. I also have a motor-generator set with which I charge my own and other batteries. The chemical division I think is fairly complete. It contains a retort, pipettes, a burette, flasks, beakers and all reagents necessary for any ordinary experiment or analysis.—also tripod, ring stand, porcelain crucible, evaporating dishes, mortar and pestle, U-tube, drying tubes, conical and cylindrical graduated, hydrometers, balance, etc. The electrical division contains among other things, a motor, audions, generators, etc., also an arc, light, resistance, storage, transformer, telephone transmitter and that inevitable collection of miscellaneous articles commonly known to the profession as "junk." I also have a set of Marconi-Victor Code Records and receive at a speed of from 15 to 20 words per minute.—Wm. H. Moore, Charleston, W. Va.
A QUEER man you will find him, Captain A. J. Stokes, deep and studious, yet a man of the world of sport and levity. He has nosed into every port in the seven seas and has seen the Amazon River looking east. It is needless to say he is independ-

“I have smoked a carload of Havanas over this subject”—he lit a cigar and lollled back in his chair—“from books and men I have gained some certain amount of knowledge concerning our ‘Juice’.

“Way back in the dawn of History, when the dim diffused light of the dawning day of experience made its vague appearance thru the hydrous canopy that surrounded our terrestrial abode, the unknown force manifested itself before unseeing eyes. According to some authorities, we are not informed of any observations until a Thales of Mileitus, only six hundred years before Christ, carved his discoveries of the funny things that amber would do when rubbed.

“Also a bird by the name of Theophrastus, who seemed to be an authority on gems, noted that when he shined some of his sparklers on his pant—(oh, excuse me! That duck wore a tablecloth) that the said sparkler would attract small objects like pins in balls and dust from his culinary garb. Besides Thales and Rastus and a very few other guys who were ‘on’, old Jope himself made the rith halls animated by the frictional performance engendered by lightning.

“That meant to her no more nor less than AIBERT! Here she would probably jerk an amber dodangle from her enchanting locks and sneer, ‘How could this sting me here!’ clapping her jeweled digits on an also jeweled hip, ‘You are dismiss from court. Lack of evidence! Whereupon you would be forced to consider yourself at bay. That was a way Cleo had about her—right or wrong.

“Nevertheless you would be right and Galvani would not be as skeptical as the Queen. No doubt, he would shuffle it whole and believe you outright. Then he would more than likely demonstrate his recent discoveries on the freshly murdered frogs and calves. Of course, the Bologna physician was deluded. We all know that a Prof. from the Pavian University had to set the popular right after Doc’s assertion

“Andy Ampere, Whom Thanks Are Due for Such Latter-day Questions as: ‘How Many Amperes Has a Volt?’”

“Mike Faraday, Who Successfully ‘Vamped’ Dame Electra Out of a Batch of Her Darkest Secrets.”

“Funny it took so long from Creation before the old timers ‘got hip’ to those primary examples, isn’t it? But I suppose that is what the bunch that will be here years anon will say of we present moderns.

“Of course Cleopatra must have drawn sparks from the red nose of some enamored Gaul when she shuffled across the Persian rug and did a Can-can before the Hun’s grandad, some spotty morning on a winter visit up in Gallia. We know that it was static electricity, but the Egyptian Boss didn’t. Neither did the Dutchman. As for that bird—it probably struck him as a severe charm of his friend, Miss Ptolemy, esq. Had you been there and slip her the info that we have christened ‘Electricity’ that caused the prickling spark to play between Her Royal Iluim and Dutch’s crimson lock, she would have looked at you as foolishly as could have been possible for such a sagacious female as the daughter of the Nile to look, and perhaps confess that you were talking rag-time to her. She might proffer the chatter, were she in the mood, that as near ‘Electricity’ as she could come was the Greek noun wëptor and the Latin Electrum, and

“Prof. Volta of WET Battery Fame. This Bird Would Have Invented a DRY Battery Sure as Nails, Even if He Had Lived in ‘Bone-dry’ America.”

“Benny Franklin, the Lightning-rod Kid,” essentially wealthy. Yet it is evident that he has a speaking acquaintance with the more serious things of life, and has thumbed the pages of History and Science in his speedy course of life.

-To-night he sat across the fireside from me at the club. In his hand he held a copy of a current electrical periodical. Seeing this, I ventured to ask, “What have you framed up in your noggin as being the right dope on the origin, use, nature and future of Electricity?”

He looked over at me and smiled a quaint smile. “That was just the sort of thing I was thinking of, the nature and future of the something we are wont to call ‘Electricity’—but how happened you to ask? “Oh, I don’t know,” I replied. “I was just wondering about it myself—and I just wondered what you entertained as to it.”

“This Tiled Roof—the Hon. W. Gilbert—is Guilty of the Term ‘Electricity’.”
The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of each question to be written on; matter must be typewritten or else written in ink, no penciled matter accepted.
3. Diagrams, etc., must be on separate sheets. Questions addresst to this department cannot be answered by mail free of charge. A nominal charge of 25 cents is made for each question. If the questions entail considerable research work or intricate calculations a special rate will be charged. Correspondents will be informed as to the fee before such questions are answered.

COLLINS-SANCHEZ HIGH FREQUENCY 3-INCH SPARK APPARATUS.

(983) George Litty, West Phila., Pa., inquires:

Q. In the November, 1915, issue of the Electrical Experimenter you publish an article on "High Frequency Currents and Apparatus," by H. Winfield Secor. Fig. 2 shows the circuit of a Collins-Sanchez high frequency circuit. I would like to have the following questions answered in the "Oracle".

1. The resistance of the magnat coil and how to construct it.

10,000 METER LOOSE COUPLER.

(984) Paul H. Gelser, Roseville, P. T., Cal., writes for data on a 10,000 meter loose coupler.

A. I. We give below data regarding the construction of a loose coupler for 10,000 meters:

Primary, 8 x 1/2" wound full No. 24 s.c.c. wire.

ODD PHOTOS WANTED AT $1.00 EACH!!

Now is the time to make your Kodak pay for itself in a real practical way. We are interested in photographs of radioing-the-ordinary electrical, radio and scientific subjects and are willing to pay $1.00 cash for every one we can use. Please have the photographs well reproduced in a magazine, a photograph should be particularly sharp and clear. Of course, if a subject happens to interest us particularly well, we can have the photo retouched. For the general run of subjects, however, it does not pay to go to such expense. Therefore, please take pains to properly focus and expose your pictures. It often happens that a really mediocre subject will photograph well and cause approval on an excellent subject poorly photographed. And don't send us plate film "reproduced", send unmounted or mounted "prints", preferably a light and dark one.

As to what to photograph: Well, that's hard for us to say. We leave that up to you, and every reader now has the opportunity to become a reformer of the latest delinquent in the realm of Electricity, Radio and Science. But, please remember—it's the "odd, novel or practical shots" that we are interested in. Every photo submitted should be accompanied by a brief description of 100 to 150 words. Give the "facts" don't worry about the style. We'll attend to that. Enclose stamps if photos are to be returned and place a piece of cardboard in the envelope with them to prevent mutilation. Look around your town and see what you can find that's interesting.

Address photos to—Editor "Odd Photos", Electrical Experimenter, 233 Fulton Street, New York City.

LOW VOLTAGE, HIGH AMPERAGE DYNAMO BRUSHES.

(986) John Voorhees, Jr., Kennett Square, Pa., says:

Q. I have a low voltage, high amperage dynamo fitted with copper leaf brushes. How can I apply carbon brushes?

A. 1. Concerning the replacement of the copper leaf brushes on your small dynamo by carbon or woven wire brushes, the appended diagram, we believe, will cover your requirements very nicely. Many of these small dynamos are successfully changed over in this way. The brush holders being either of the round or square pattern, should be clamped or some way secured to the brush holder studs on your present rocker arm. You can obtain the round type brass brush holders complete with springs and brushes from any electrical repair shop or electric fan dealer.

NITROGEN RADIATOR FOR ELECTRIC HEATING.

(985) Harry B. Genders, Wednesbury, England, asks the Oracle Department: Q. 1. I would like to know if you would give me a few particulars regarding the Portable Electric Nitrogen Radiator, as described on page 464 of November, 1918, issue of "E.E." I presume the radiator is simply filled with nitrogen at ordinary atmospheric pressure. I should like to know if an ordinary hot water radiator could be converted to one of the above type? Also would it do if simply filled with air at atmospheric pressure? I suppose the efficiency would not be as great as with nitrogen filling.

A. 1. With reference to converting an ordinary hot water radiator to an electrically heated type, most probably with a little ingenuity you could do this, but, of course, it will not be as efficient as the nitrogen filled radiator. There are several electrical radiators on the market on the principle of the simple form as you suggest, i.e., comprising nothing more than a suitably protected and insulated electrical heating element, which is caused to either heat up water with which the radiator is filled, or in some other way to produce heat in the ordinary manner.

This High Frequency Coil Operates on 110 Volts A.C. or D.C. It Produces a 3" Flaming High Frequency Spark. The Interrupter Coil Has an Iron Wire Core 3/4 Diameter by 3 1/2 Long, Wound with a Coil 2 1/2" Long of No. 28 D.C. Magnétique Wire. Outer Diameter of Coil 1 3/4". Vibrator Fitted with 1/2 Diameter Silver Contacts. Condenser Sheets of Tinfoil 2 1/4 x 3 1/2. Placed Between Mic'a Sheets 6 Mils Thick and Measuring 3" by 4 1/4".

(2) The capacity of the condenser.
(3) The size of the condenser.

A. 1. We give herewith diagram of the Collins-Sanchez high frequency apparatus, including the dimensions of the interrupter magnetic, the condenser, and the proportions of the Oudin high frequency coil, the latter being best encased in a wax mould thoroly surrounding it.

Secondary, 7/8 x 1 1/2" wound full No. 30 s.c.c. wire for crystal detector.

For use with audion, wind full with one layer of No. 34 s.c.c. wire.

Proper Setting of Carbon Brushes on Low Voltage Dynamo. These Replacing Flat Copper Brushes Which Did Not Prove Satisfactory.

When the round type of brushes are used (Continued on page 802)
FREE Test Lesson In Draftsmanship

Send for this free lesson which explains the Chicago “Tech” method of teaching Draftsmanship by mail. Positions at big salaries are now waiting for competent men. Even draftsmen of limited training and experience are snapped up and paid good salaries. If you are dissatisfied with your opportunities, learn Draftsmanship. Chicago “Tech” will train you in the most practical way in the shortest time. Mail the coupon today and let us tell you about the Chicago “Tech” method. The free lesson will show you how well equipped you are to follow Draftsmanship. Enroll in the course only if you decide that you can take it up to advantage. No cost, no obligation on you to make this investigation. Send the coupon.

$25 to $100 a Week

Draftsmen always command good salaries. And now when American industries are to be called upon to meet vast foreign and increased domestic demands, the opportunities are greater than ever. This is the time for you to prepare for a better position—a higher salary.

Come to the College or
Learn At Home

Hold your present position while training. Our experts will instruct you by mail. Only your spare time is required. You are directly under practical draftsmen and engineers. You are taught exactly the work required in the drafting rooms of big concerns. No time put in on unnecessary studies. This means thorough instruction and early graduation.

Easy Payments

The fees for Chicago “Tech” Courses are very moderate—and you can pay on easy terms. And also, you obtain in a few months what it would take several years to acquire by ordinary methods. You can get an early start. You are soon ready to take a paying position and to quickly get back the cost of your course. Then keep on earning more.

FREE Instruments

Every student of the Chicago “Tech” mail course in Draftsmanship receives this set of instruments, or a cash credit in case he already has a set. These instruments are of the same make and sizes as are used by high salaried experts in drafting rooms of factories, shops, railroads, etc. You use them while learning—then take them right into your practical work.

Auto and Gas Engine Course

All about automobile mechanisms—the construction, operation and REPAIR—taught by mail. You train directly under the Chicago “Tech” automobile experts. Specially opportunities open now. Send coupon and get all the facts.

Learn All This in Spare Time

Principles of the Automobile. Every mail, make clear the broad purposes of and the working parts of the automobile. Engines, clutch, drive, doors, suspension, etc.

Gasoline Engines. All about the different types. A complete course in gasoline engine theory. Gasoline engine engineers are needed.

Power Plants and Transmissions. A clear,限期, complete course in the theory and actual construction of the gasoline engine. Power transmission, drive, etc.

Carburetors and Fuel Supply Systems. All methods demonstrated, Full values. How to keep, adjust and test these vital systems, the carburetor, fuel system, etc.

Magneto Ignition. Principles and practical operation of various types and makes of automobile magneto ignition systems completely illustrated.

Starting and Lighting Systems. All methods demonstrated, full values. How to test, and when to replace, the magneto, battery, glow lamp, etc.

Know How to Find and Fix Troubles

A complete instruction in auto repair work. Realize you for high pay or to plant a business, and ascend to the very top. Practical pointers make up a career which will keep you in demand and make you safe.

WRITE Send the coupon and get catalog and all information about the Course, the fee and the easy terms. All this sent on request. Mail coupon now.

Send the Coupon—Now

The sooner you are prepared the sooner you will be holding a job that pays a large salary and opens the way to advancement. Many executives, general managers and superintendent begins as draftsmen. Other institutions ask you to pay first—and then to find out later how well qualified you are for this profession. We send you the free lesson first and place you under no obligation at all. Discover your qualifications before you pay anything.

The coupon will bring the free lesson, free. Also information about the profession of Draftsmanship and detailed facts about Chicago “Tech” methods, terms, etc. Mark with X the branch of work you are interested in—or if in doubt about which take, write a letter stating facts about yourself and asking our advice. We will be pleased to send the coupon or letter today.

Preserve Your Phonograph Records!

Build Your Own PHONOGRAPH
It's Easy With Our Help
A few interesting work saves many dollars and gives you a machine exactly to suit your ideals. We furnish plans and instructions, and you work on your own time. The price of building phonographs depends on your own discretion. Write for Our Free Book: "How to Build Your Own." Plans are also available for our ready built Choraleon.

CHORALEON CO.
203 Munger Bldg., Elkhart, Ind.

FREE $20 Violin, Hawaiian Guitar, Ukulele, Guitar, Mandoline, Coronet or Banjo

Wonderful new system of teaching note music must be seen. To fruit quickly in each locality, we give a free expert teacher, Mandolino, banjo, violin or Hawaiian guitar. Very small charge for lessons only, you receive immediate access to original methods. Write for our free book, "The Choraleon School Music, Book". Chicago, Illinois.

ELECTRICAL

THE ORACLE.

(Continued from page 800)

A sufficient number of these should be employed to take care of the comparatively heavy current of these low voltage machines. Sometimes two or three can be placed in a row on most of the small commutators. Also a very good brush for this machine, and one of the very best that the Editor of this Department has come in contact with his extensive motor repair experience, is that having a special grattie-carbon brush body about 1/2" wide by 3/8" thick, with a woven wire core or center.

WINDBINGS FOR SMALL A. C.

WE wish to introduce to the public the new Sonora Needle, and we are confident that it will be a great improvement in the Arena. We have been using them for some time, and have found them very satisfactory.

Sonora Semi-Permanent Silvered NEEDLES

Replace steel needles! They play 50 to 100 times longer than steel. Use Sonora Needles for lower tone, greater economy, convenience and for longer record life.

Load-Medium-Soft
30c. per card of 5
All other sizes.

Sonora Phonograph Sales Company, Inc.
GEORGE E. BURBRECHT, President
270 Broadway, Dept. 6, New York

CAUTION: Be sure that the needle is properly inserted into the needle seat.

ELECTRICAL EXPERIMENTER

March, 1919

WINDINGS FOR SMALL A. C. INDUCTION MOTOR.

(987) Harry Ostness, River Falls, Wis., asks:

Q. 1. The diagram herewith shows an induction motor which I wish to wind so as to operate satisfactorily on 110 volts, 60 cycles, A. C. Can you give me data for starting and running coils?

A. With regard to your query concerning the rewinding of a small 12 pole A. C. induction motor, we are pleased to give you the following suggestions on your problem:

To start with you might try winding each of the stator poles with a coil composed of four layers of No. 20 D. C. C. magnet wire. These coils are best wound on a form in a small winding jig or in the lathe, and tied by means of four springs, one in each corner of the form so as to hold the coil in shape. In repair shop practice, these coils are sometimes wound on a form in the manner mentioned, and afterward taped with white cotton or linen tape, using narrow tape in this instance. Only a wide tape can be obtained, then this should be split. The coils may be given a coat of black asphaltum, but in most cases a piece of felt paper is wound around the pole-piece and the coil placed over this, and after all the coils are in place, the windings are treated with a liberal coat of orange shellac. All of these running coils should be connected to give alternate north and south poles.

Regarding the starting coils, these may be composed of about 20 turns of No. 26 D. C. C. magnet wire, wound on a form so as to slip over one side of the pole-face. The coils are placed in series in turn to give alternate north and south poles. It may be said that the running coils and the starting coils are wound on the two circuits; the starting coils being invariably provided with an automatic centrifugal switch mounted on the shaft of the motor so as to open the circuit as soon as the motor has attained synchronous speed.

In this connection, we believe you will do very well to try the copper or brass shading plates which are also extensively employed. These are used on a number of the commercial A. C. induction motors below 1/4 h. p. in size. They are about 3/8" thick and have a slot in them so as to fit over the half projection of the pole shoe. One or two laminations on either side of the pole shoe are then bent over and hammered down to retain the plate in position. The rotor will revolve in the direction of the plates; to reverse the direction of the rotor, the plates should be placed on the other half-projection of the pole shoe so as to face in the opposite direction, or else the stator frame should be reversed in position. All of the shading plates, of course, must be placed on the same relative side of the stator poles in any case. To reverse the direction of a motor supplied with a starting winding instead of shading plates, the leads connecting this circuit to the 110 volt supply are reversed.

THE ARMSTRONG AUDION CIRCUIT.

(988) John M. Burrell, Pittsburgh, Pa., asks:

Q. 1. Data on condensers, inductances, etc., for the "Armstrong" regenerative audion circuit.

A. Herewith is a typical Armstrong regenerative receiving circuit. As all dimensions are given in the diagram, we deem it unnecessary to go into further details.

![Diagram of Armstrong Regenerative Audion Circuit](image)

**ARC WELDING QUERIES.**

(989) Wm. S., Torrington, Conn., writes:

Q. 1. Can arc welding be done with regular city lighting circuits? If yes, A. C. rectified to D. C.? Would common iron wire resistance be sufficient or would a special low voltage transformer be necessary?

Q. 2. Can oxygen be produced by the electrolysis of water by 110 volt D. C.? Would a solution of acid be necessary to act as a conductor of the current? Is it possible to use for welding, brazing or burning out carbon in motors? Could any useful amount of oxygen be obtained?

A. 1. Concerning arc welding you will find very valuable information on this work contained in a recent paper by Mr. Horner in the Electric Welding of Steel ships read before the Philadelphia Section of the American Institute of Electrical Engineers. Copy of this paper can be obtained by mentioning the subject and the author's name to the Secretary, Mr. F. L. Hutchinson, A. I. E. E., 33 W. 39th Street, New York City.

Also you will find a very good article on this subject in the December issue of the Electrical Experimenter. A typical arc welding outfit is illustrated and described therein, including A. C. motor and D. C.

(Continued on page 804)
“Humanize”
Your Talking Machine

If you have been using an ordinary reproducer on your phonograph or talking machine, you have been missing the real music. You have failed to hear the beautiful overtones which musicians listen for—you have heard but a poor imitation of the composition as originally played or sung by the artist. The true tone coloring is not—can not be—faithfully reproduced by ordinary reproducers.

It took ten years of hard study and constant experimenting to develop and perfect the one reproducer that does faithfully bring to life all there is in the record. It is called the

Ellis “Music-Master” Reproducer

Now being used by thousands of music-lover owners of talking machines—and every one of them enthusiastic in praise of its wonderful merits

Below we reproduce just a few of the thousands of unsolicited testimonial letters we have received. Read them—they are more convincing than anything we could tell you.

What Satisfied Users Say

MR. J. H. ELLIS,
Milwaukee, Wis.

My Dear Mr. Ellis—
It is delightful to listen to records played with your “Music-Master” Reproducer; it brings out certain niceties and details I had decided could not be recorded or else reproduced.

Your reproducer certainly is a marvel.

Last week when Galli Curci sang here with the Chicago Opera Company it was necessary for me to explain to one of my advanced students that it was not Galli Curci, in person, singing in your laboratory next to our “Studios” but one of her records played with your “Music Master” reproducer.

This proves that the little invention speaks for itself which should be very gratifying to you.
Wishing you success, I remain,
Very truly yours,

FLEETWOOD A. DIEFFENTHAELER, Director.

A Chicago customer says—
“Your latest Ellis “Music-Master” Reproducer reached me several days ago and I have tried it out in every shape and form and it is simply a revelation, a wonder, a thing of beauty and a joy forever. I am delighted beyond my fondest dreams. I tried one of Caruso’s hardest records with the loud steel needle, also my hardest band records and never a blue or discordant note.

“I spend my spare time enjoying the marvels of the “Music-Master” and the harder I try it the harder it is to stop. We have never enjoyed our records as completely.”

One enthusiastic user says—
“There is more music in my records than I imagined possible until I discovered it by means of your Reproducer.”

Another user says—
“The “Music Master” Reproducer brings out the musical and tone coloring true to Life.”

And another—
“The reproduction of the human voice is wonderful and the rendition of violin as true to the artist’s performance as when making the record even to the down touch of the bow.”

Still another says—
“I would not sell my Ellis “Music-Master” for a thousand dollars unless I first get another equally good.”

J. H. ELLIS, Patentee and Manufacturer
P. O. Box 882 MILWAUKEE, WIS.

You must hear the “Music-Master” to appreciate its great merit

Words cannot convey to you an adequate idea of how much this wonderful little device will do to improve the playing of records. You must see it—hear it—compare the effect with any and all other reproducers you know of, then you will understand why every music-lover owner of a phonograph who hears the “Music-Master” Reproducer wants to own one.

For all machines—
Plays all Records

No matter what style, size or make of talking machine you have, if it uses disc records you can use the Ellis “Music-Master” and enjoy the real music. The “Music-Master” is easily put on any machine—it does not harm the records; in fact it prolongs their life, because it is much lighter in weight than other reproducers.

Write Today for Full Details

Fill out and mail the coupon below. If you will also enclose 5c in stamps, I will send you a valuable little booklet entitled “Pointers on the Care of Talking Machines and Records.” But, send the coupon for full details about the “Music-Master” Reproducer whether or not you wish the booklet.

MAIL THIS COUPON NOW!

J. H. ELLIS,
P. O. Box 882, Milwaukee, Wis.

ELECTRICAL EXPERIMENTER

THE ORACLE.
(Continued from page 802)

A handy pocket manual primarily intended for the use of Wireless Operators, but equally valuable to the perennial student. It thoroughly handles Marconi equipment and as such serves its purpose admirably. Large, clear diagrams covered in many other previous works on this subject so that the operator has nothing to do but to glance at the diagrams to have an idea of the ground covered. General information, principles, etc., are also treated, as well as making the apparatus, inspections, etc. Preparing installations for laying up, transmitting apparatus, marine switching and cable connections, rectifiers, converters, keys, transmitters, condensers, disc distributors, receiving apparatus, the care of the same, both the replacing of parts, the aerial and its fittings, the file, the diode, etc., are treated.

A very complete chapter on the storage battery is included, which explains how to take care of the battery while in actual use, also some remarks on how long it can be kept in storage without being out of service for any length of time. A brief concluding chapter treats of the Marconi wavemeter and its addition to the measurements aboard ship, such as the wave length of the transmitted and incoming wave lengths.

This book is very brief in its explanations and presupposes only a very slight previous knowledge of the theory of radio circuits and apparatus. Similar books have appeared on this side of the Atlantic which have been much broader in scope so far as wave length and ship radio equipment is concerned at any rate.

MODERN WIRING DIAGRAMS AND DESCRIPTIONS, by electrical workers, by Horstmann & Touseley. 298 pages, 207 illustrations, size 6¼ x 4½ inches. Cloth bound $1.00, leather bound $1.50. Published by Frederick J. Drake & Company, Chicago, Ill.

This work forms a tried and true friend of the electrician and wiring professor. It contains two hundred diagrams of electrical apparatus covering every conceivable device with which the every-day electrician is called upon to work. Diagrams and connection for various switches and telephone circuits, including the inter-communicating system so widely used in offices. One section deals with connections of telegraph instruments, especially the United States patent telegraph. Another section on the connections for electrical writing instruments made in America and Great Britain in conjunction with the connections of X-ray and gas lighting apparatus, primarily that used in telephone offices. Here are located faults on circuits, electric lighting, and a host of other connections for two- and three-way switching, house and office building wiring, etc.

Greatest Electrical Books
Now Brought to Your Home!

7 Big Volumes—Written by 27 Great Authorities—Yours for 7 Cents a Day

This is the hardest way to learn Electricity through your own experience. The easiest way to learn through the experience that others have paid for in time and money. Here in practical, easy-to-understand form, you get the benefit of what 77 greatest electrical authorities in America and all over the world have learned, and you get this vast fund of experience in convenient book form, so that you can read and study in your own home in your spare time.

This is the greatest opportunity of your life to become an electrical engineer, sub-station operator, dynamo tender, or to get any one of the other big-pay jobs in the electrical field. For less than you spend for tobacco or movies, you can train yourself step by step up to the jobs paying $3,000 to $5,000 a year.

Shipped on Free Examination
No Money in Advance

Just glance at the partial list of contents of these 7 volumes in the panel at the left. Think how much there is for you in this great home-study library of electricity. Then write at once for the books themselves. Examine them in your own home for a week. Send them back if you are not satisfied. But if you decide to own this pay-reading set, send only $2 and then only $2 a month until the special half price is paid. Examine the books—see how they take you through every detail of each special branch of electricity. See how they give you all the necessary tables and formulas in simple, untechnical form. Note the frequent test questions which enable you to examine yourself. Note the 2,000 illustrations, full page plates, diagrams, etc. You be the judge of their value to you.

HALF PRICE—NOW

For a limited time we are offering this remarkable self-instructor Electrical library at half price. Regular price $25—special price $13 on easy terms of only 7 cents a day. With each set we include a year’s Consulting Service Membership free—worth $12. The 7 volumes contain 5,000 pages, each 7 x 10 inches, bound in American Morocco, Gold Stamped.

Mail Coupon—Send No Money

If you are interested in electricity you need these books. You will prize them for the new up-to-date information they give you on every phase of electrical work. We ship the 7 volumes right to your home on your simple request. Send no money until you are satisfied after 7 days free examination. Put your name and address on the coupon now and send at once before this offer is withdrawn.

Mail This Coupon Now

AMERICAN TECHNICAL SOCIETY
Dept. E3383, Chicago, U. S. A.

Please send Cyclopaedia of Applied Electricity for seven days' examination. I will pay shipping charges. I will send $2 within seven days and $2 a month until I have paid $19.80 or notify you and hold the books subject to your order. Title not to pass until fully paid.

### Experimental Physics

(Continued from page 285)

**Experiment 110.**

In conducting experiments with the electroscope all parts except the gold leaf system should be grounded; since any part insulated is likely to become charged slightly and owing to the extreme sensitivity of the instrument the gold leaf system would thereby be disturbed.

We will now proceed with the fundamental experiment of charging and discharging the electroscope. Rub an electroscope rod or ordinary fountain pen with cat's fur or flannel or your coat sleeve (or a glass rod with silk.) Bring this charged rod in contact with bent rod B, at same time turning B so that it touches the rod G. Now by means of the charged rod charged charge will travel thru the conductor B to G and therefore G and the gold leaf, having the same charge, will repel each other. Since the rod G is rigidly fastened and the leaf H is not, H will spring away from G. Now by means of the charged rod bend rod C away to position of figure 99-B. Since G and H are insulated from the rest of the electroscope the charge cannot leave and the electroscope is now charged. To discharge touch the finger to the bent rod and bring the rod into contact with the gold leaf system H-G. The charge will pass to the finger and thru the body to the earth.

**Experiment 111.**

After the electroscope has been charged and allowed to stand awhile we find that it loses its charge slowly but surely. The rate at which the charge is lost, is called the natural leak of the electroscope. To measure the natural leak, set up a telescope pointing at the window of the electroscope, as in figure 100-A. A paper scale may be attached in the electroscope behind the gold leaf system so that the field of view of the telescope will appear as in figure 100-B. Take readings of the telescope at equal intervals of time and the average will give a good approximation of the natural leak.

**Experiment 112.**

We cannot determine the presence of radio-active substances in a compound or mixture by chemical means, because these substances are found in such small quantities. We may, however, detect their presence as Becquerel did by the use of the photographic plate or by the use of the electroscope, by which method Madame Curie discovered Radium. (See Experiment No. 108). Let us recall the passage of electricity thru a liquid. The liquid ionizes and we call it an Electrolyte. In a similar manner, a gas ionizes, the velocity of the ions in the gas being tremendously greater than that of the ions in the electrolyte. This explains the natural leak of the electroscope, i.e., the air is somewhat ionized, depending upon atmospheric and other conditions.

Place the electroscope near the stove or radiator. We find that the natural leak of the electroscope is the same, i.e., heat does not cause any additional ionization of the air. If however a Bunsen flame is placed

The Man Who Wouldn't Stay Down

$15 a Week
$18.00 a Week
$40.00 a Week
$100.00 a Week

He was putting in long hours at monotonous unskilled work. His small pay scarcely lasted from one week to the next. Pleasures were few and far between and he couldn't save a cent.

He was down—but he wouldn't stay there! He saw other men promoted, and he made up his mind that what they could do he could do. Then he found the reason they were promoted was because they had special training—an expert knowledge of some one line. So he made up his mind that he would get that kind of training.

He marked and mailed to Scranton a coupon like the one below. That was his first step upward. It brought him just the information he was looking for. He found he could get the training he needed right at home in the hours after supper. From that time on he spent part of his spare time studying.

The first reward was not long in coming—an increase in salary. Then came another. Then he was made Foreman. Now he is Superintendent with an income that means independence and all the comforts and pleasures that make life worth living.

It just shows what a man with ambition can do. And this man is only one out of hundreds of thousands who have climbed the same steps to success with the help of the International Correspondence Schools.

What about you?

Are you satisfied merely to hang on where you are or would you, too, like to have a real job and real money? It's entirely up to you. You don't have to stay down. You can climb to the position you want in the work you like best. Yes, you can! The I. C. S. is ready and anxious to come to you, wherever you are, with the very help you need.

Surely when you have an opportunity that means so much, you can't afford to let another priceless hour pass without at least finding out about it. And the way to do that is easy—without cost, without obligating yourself in any way, mark and mail this coupon.
ELECTRICAL

Learn ELECTRICITY

There is a wonderful opportunity right now for boys who like electricity. Boys who are ambitious and will train themselves in spare time can step into positions just as soon as they are ready. Good salaries are offered to start with splendid chances for rapid promotion.

For 27 years the International Correspondence Schools have been training boys for success in electricity and over 200 other subjects. They will help you prepare right at home for a position in the line of electrical work you like best—or in any other work that appeals to you.

Thousands of boys, through I. C. S. training, have stepped into fine jobs, but never opportunities so great as now.

Let the I. C. S. help you. Choose the work you like best in the coupon below, then mark and mail it today. This does not obligate you in the least, and will bring you information that will start you on a successful career.

(Continued from page 806)

EXPERIMENTAL PHYSICS.

near the electroscope, we find that the electroscope discharges rapidly. The Bunsen flame ionizes the air very rapidly. A small quantity of radium must still discharge the electroscope very rapidly, showing that radio-active materials have the ability to ionize the air. The larger the amount of radio-active material the faster the rate of discharge of the electroscope. A pinch of Uranium Oxid in the electroscope chamber, will ionize the air so rapidly that the leaf will fall practically instantaneously.

Experiment 113.

A third test of the presence of most radio-active substances is the "Fluorescence Effect"—which some of them have upon certain compounds, especially Zinc Sulphide. And of the various compounds given off as alpha radiations (see figure 102) will cause a zinc sulphide screen to fluoresce. If the screen is observed through a sufficiently high-power magnifying lens, or microscope (say ten or fifteen diameters magnification), the continuous soft glow of the zinc sulphide by the eye becomes, on magnification, hundreds of tiny flashes of light, not unlike the sparks obtained by striking a zinc sulphide screen. Figure 101 shows the Spinthariteoscope, which can be easily made by the reader. A is small metal tube with a hole, S, in its cap. E and F are the lenses of the fluorescent screen on the cap of tube B. D is a small particle of the radio-active substance. A practical use of the fluorescent effect of alpha particles is familiar to all of us in the radium paint, luminous dials, etc. These compounds consist of specially prepared zinc sulphide mixed with about 2000 parts of radium bromide, or a radio-active compound having an equivalent of alpha-ray activity. Alto the period of half decay of radium is nearly 20,000 years, see table 102, the luminosity of the compound falls off, due to the fact that the zinc sulphide loses its power to luminesce, but not because it has become radioactive. Some specifications for luminous paint, as for government work, stipulate that the zinc sulphide and radio-active substance be mixed in such proportions that the average useful life of the paint will be from 8 to 10 years.

The discovery of radio-activity has given us a vast field for research and as a result the physicist has been able to make substantial progress in his investigations by exploding and out as fragments, the alpha and beta particles. Alto the energy liberated by these explosions is far higher. The most weight of the radio-active substance has been detected after the liberation of the energy. J. J. Thomson computed that the disintegration of one gram of radium would liberate sufficient energy to raise a million tons 300 feet. See Fig. 103. If only this energy could be trapped, and research shows the possibility of it, Garfield and his coal-house gang would lose their job, for who would use ten tons of coal when one gram of radium would supply the equivalent heating table. Value 102 gives interesting data concerning the radio-active substances. Table 102 gives interesting data concerning the radio-active substances. The first row contains the name of each substance. The second column gives the second on disintegration and the second, etc. The second column gives the kind of radiation given off by the respective substances, the third column tells how long it takes for the substance to disintegrate to half of the original amount. This half-period means the time after which, one-half of the substance in question will have disintegrated. After 400,000 years, one-half of the remainder, or disappeared, etc. The total life of pure Nudium is computed from this law to be 22,000 years.

(Experiments continued)

HISTORIC ELECTRIC SWITCH-BOARD AND DYNAMO.

(Continued from page 778)

field magnet type with surface wound armatures. There are quite a number of these generators still in existence in various parts of the country, and as the designer, it should be said that they perform their duty very well indeed, considering the time at which they were built, for thirty to thirty-five years in the electrical industry, we might almost say, witness the entire development of the whole scheme of electrical generating plants. The advantages of utilization of power, under the directorship of such men as Edison, Thomson, Houston, Tesla, Westinghouse and Sprague.

The modern switch-board shown in the photograph, contains four box-type field rheostats, and it is peculiar to note that they are mounted on the face of the board instead of in the rear, as in present day practise.—Photo by Richard Nelson.

THE TESLA EGG OF COLUMBUS.

(Continued from page 775)

Tesla had other surprises for his audiences, which were even more wonderful. So, for instance, on holography, the glass, in the foreground, was used to operate wireless motors, lamps and other devices, and, in the background, he showed a wonderful installation of very high potential phenomena, as streamers of great length.

ULTRAVIOLET ENERGY AND ITS USE.

By M. Luckich, Physicist, Nela Research Laboratory.

Since the discovery of ultraviolet rays, more than a century has passed, and the laws and properties have been subjected to a great deal of investigation. However, notwithstanding the extensive literature on the subject, the investigator of the Author, who says in his book on Photo-chemistry: "We are only at the beginning of the consequence of the radiation of the light, as distinct from the unconscious enjoyment of them."

Owing to the many unique properties of ultraviolet rays, they are valuable in certain scientific investigations, tests, and industrial processes, and it appears certain, that with the progress of the science, and the knowledge and of media transparent to the, the usefulness of ultraviolet energy will be rapidly extended. The problems in which these unique properties may be utilized are manifold.

As to Sources:—There are many sources of ultraviolet energy, but few are powerful enough to be widely useful. The ideal source, which emits a continuous non-banded spectrum of high intensity through the entire ultraviolet region does not exist. Some of the sources are here ranked in order: magnetite arc, old mercury arc, new mercury arc, and carbon arc.

The blue flame arc emits ultraviolet energy very strongly. It is a simple matter to construct an arc which will emit ultraviolet energy strong enough for control is satisfactory. An iron rod and a carbon rod may be employed successfully for these poles. Iron and carbon rods may answer the purpose very well. These poles may be kept cool effectively by means of heavy brass or copper sleeves, which may be wound around the iron rods as the latter are consumed.

Uses of Ultraviolet Rays:—Irradiation of air: powerful bacteriical agent, kill germs in the air, effective in preventing the growth of germs to control the utilizations, and to brine the skin. In industrial processes such as acetylene and arc welding, which are attended by powerful ultraviolet energy, there is a demand for eye-protecting glasses.

You know how often you have wished that you could write shorthand.
You realized what it meant to busy executives and to business beginners—in efficiency, advancement and increased earning power.

But like thousands of others you found the long, weary, menial task of study, the memory tax, the mental strain and the high cost, in time and money, of the old systems.

Now you can have your wish. Because, all that you dreaded is done away with in the Paragon Method of Shorthand. Instead of committing to memory something like 4000 word-signs and contractions, which in other systems largely depend for their meaning upon the position in which they occupy, you have only 26 word-signs to learn in Paragon. The entire system consists of:

The Paragon Alphabet:

Twenty-six simple word-signs:

<table>
<thead>
<tr>
<th>Six prefix contractions:</th>
</tr>
</thead>
<tbody>
<tr>
<td>One general rule for abbreviations:</td>
</tr>
</tbody>
</table>

THAT IS ALL. The simple explanations and exercises are divided into seven lessons, the principles of which one can grasp in one evening.

Speed will develop pleasantly as you make daily use of your quickly acquired knowledge.

This is the Paragon System. Thousands have learned the 7 lessons in 7 evenings. See for yourself how perfectly simple it is. Stop right here and study the specimen lesson shown above at the right.

Now you see how easy it must be to learn Paragon and how quickly one can equip himself with this great modern instrument of Efficiency.

Everybody Can Use Shorthand

Our records show that in addition to the thousands of women and men who need shorthand as a help in their business careers, other thousands—business men, professional men, students, clergymen and literary folk—would like to learn Paragon Shorthand as a time-saving convenience. Still others fathers and mothers would like to give their sons and daughters this wonderful advantage in order that they may be able to self-supporting any time it may be necessary.

Many of these persons who have not a direct need for shorthand but want it as an instrument of efficiency and a daily time-saver would buy the complete course of Paragon Shorthand at a popular selling price.

A Valuable Accomplishment Quickly Learned

Thousands of young, ambitious men and women who have failed to learn the old, complicated forms of shorthand have learned Paragon with ease. They have since become court stenographers, reporters, assistants to business heads and in many cases executives of prominent concerns and institutions. Thousands of grateful letters now in our files attest these facts.

Try This Lesson Now

Take the ordinary longhand letter: D

Eliminate everything but the long downstroke and you will have the Paragon symbol for D. It always writes downwards.

From the longhand letter D rub out everything except the upper part—just like—with the Paragon symbol for D. Write this circle at the beginning of each word and you will have the Paragon symbol for D.

By letting the circle remain open it will be 0, and this hook stands for 0. Write another A at the end of your line and you will have a girl's name, Ada.

From these four symbols you can write the initial and final strokes and O will remain which is the Paragon symbol for O.

For the shorthand-who-which is made it 7 strokes, you use this one horizontal stroke:

Therefore, would be Me:

Now add the E on the M, see how D and you will have Med. Now add the large circle 0, as you have Med. and you will have Med., which is een. Again use the A and W.

Now you have 5 of the characters. There are an additional 12. These are simple word-signs, six prefix contractions and one general rule for abbreviations. That is all.

Paragon is Used Everywhere

Paragon is used in the offices of the largest firms and corporations in the world such as Standard Oil Company, United States Steel Corporation and the great Railway Systems.

You can be at any point where you must know shorthand to do your work efficiently and must write shorthand—be a busy executive or be a beginning in your business work.

You know how it is. Two good reasons apply to a position—one knows shorthand and the other does not—the shorthand man wins every time. And we will apply to young women.

Remember how many of the biggest men in America got their start because they could write shorthand—Frank A. Vanderlip, George B. Cortelyou, William Loeb, Jr., Edward Lask and other men of highest achievement.

Shorthand Writers Wanted

Never before has American business felt so keenly the shortage of capable writers. Every business house is looking everywhere for shorthand men. Now you are ready to pay any salary within reason to get an expert shorthand man. salaries are steadily advancing—and yet the demand for shorthand writers has not been supplied.

Only $5 If You Keep It

Think of it. For $5 you can have a complete education in shorthand, a life-long help—not only for yourself but for your wife or children or any other relative.

You can exactly the same course that has been taken by business men for 25 years by its inventor personally by mail at a total of $5.25. With 7 lessons and the ingenious self-examinating method devised by the inventor you can learn Paragon at home under the personal supervision of the inventor.

Send No Money—Try It Free

Try it at our expense first. Simply fill out the coupon below and mail it to us and we will send you our Complete Course of Paragon Shorthand with the distinct understanding that you have 7 days after receipt of this course to either return the course to us or order the course for $5.00.

Paragon Institute, Home Study Department, 601 Broad Street, Suite 350, Newark, N. J.

You may send me the Complete Course of PARAGON Shorthand with the distinct understanding that I have 7 days after receipt to either return the course to you for your money or order the course for $5.00.

Electrical Experimenter 5-19
SORTING TOBACCO LEAVES BY ELECTRICITY.

(Continued from page 770)

duplicate of the first section, except that where a permanent step is provided in the path of movement, to prevent any leaf from returning to the starting point, but deposit it in the box provided for the longest leaves.

All boxes, ten at each side of the machine, are standing on a kind of steps, so that each one is, according to the inclination of the covers, a little below the foregoing one. As the machine is but a duplicate, the device being a double action machine, there are ten boxes for ten different sizes of leaves at each side, or 20 boxes altogether.

The contact segments on the table are movable, and the machine can thus be so finely adjusted that it will not only measure and sort the leaves, but require, but even up to a quarter of an inch if so desired. The machine is driven by an electric motor, arranged so that the table and not visible in the illustration, and by means of an electric regulator the speed of the machine can be regulated to meet the speed with which a sorter will be able to place leaves upon the feeding belt.

33 ASSEMBLED LOCOMOTIVES ON HIRE

(Continued from page 765)

expert locomotive engineers for assembling and it took the better part of a week before even one engine was complete. The locomotive had been ordered on a continuous order in the shops, as well as having all the parts of the machine carefully marked before being disassembled on this side of the border. We ordered in as many days and extra necessary work—especially when time was at a premium. Those same engines which at one time there were thirteen ships loaded with knocked down locomotives in ports in France waiting for the discharge of their cargoes.

This was the situation confronting the Shipping Control Committee on January, 1918. The locomotive problem was immedi-dately discernible. Indeed there was not way by which the complete locomotives could be sent across the ocean intact.

The ships steamed Feltoro, Cubore, and San-ter, each 466 feet long, with three great holds and five hatches, the smallest of which was 33 feet by 37 feet and the largest 39 feet by 37 feet. Each ship had a cargo capacity of 11,000 tons and was fitted with electric turbines capable of driving the ship at a speed of ten knots.

On May first loading started, and the holds of the steamer Feltoro were filled off with five layers of railroad rails and spires to secure stability and also to protect the hull of the ship. Next day a railroad float came alongside with eight assembled locomotives ready for the trip.

The problem of getting the locomotives into the hold of the ship was solved by requisitioning one of the largest cranes in the world capable of lifting 150,500 pounds in France. This derrick captain took his stand on the deck of the steamer and by the use of electric signals directed every movement of the machine, which was a single hitch, each and every one of these steel-bound monsters of the rails, was lowered and set on heavy oak planks; after which two more ooz of hay and bags of oats were packed around them.

And so seven days after the start of this great trip, there were on the waves at Brest, France, 33 large assembled locomotives and tenders, 2,400 tons of rails and splices, 2,300 tons of hay, 600 tons of oats, and fifty-three motor trucks.

WOOD FINISHING FOR THE AMATEUR.

(Continued from page 793)

either of two ways, which are known among finishers as the “quick” and the “slow” methods of polishing.

The quick method is as follows: Dip a handful of raw cotton into a mixture of half peanut oil (refined cottonseed oil will do), and a few alcohol, mix well with a rotary motion, which will give a fine lustre in a short time.

The better of the two is the slow process. After the work has been in the dead finish mentioned above, put on an extra coat of finishing varnish, allow it to dry, and rub down again with Pumice stone, washing up thoroughly after each ground rotten stone over the surface with a soft chamois skin, using a circular motion, and then dry, rub it off with the palm of the hand.

There are several other kinds of polishing, notably wax polishing and oil polishing, which may be used if desired. In wax polishing the polish is put on at the same stage that the varnish would have been applied. Using any method convenient to get the wax on the surface, the next step is, to warm the wax and apply it with a brush, the same as varnish. This gives an even coat of wax, which is then polished with a cloth. There is also a number of manufactured waxes on the market, any of which will give the desired results. The chief objection to wax polishing is that it lasting very easily, but it is also renewed very easily, hence this is not a such an objection for many kinds of work.

Oil polishing is the most durable of all, and therefore is used for table tops, counters, etc., and which is used for a number of years. The process is very simple, but heartbreaking. It consists of applying either natural or man-made linseed oil upon the surface, and then rubbing it until a polish is secured. The polishing is done by means of a piece of felt wrap around a heavy block, to give it weight.

This is about all that need be said about the various processes used in wood finishing, but a brief description of the various kinds of waxes has been omitted, as the Electrical Experimenter would not be out of place. A perusal of the list will often help determine the kind of wood required for any particular piece of work.

Birch.—Black birch takes on a fine polish, as it is close grained. Its natural color is light, so it is usually stained in imitation of oak, walnut, or mahogany. For table tops, counters, etc., it is close grained, a filler is not absolutely necessary, but when staining this wood to imitate some other, a properly colored filler gives it a better coloration.

Cherry.—This wood is very close grained, and will take a high polish. It has little tendency to warp, and because of its close grain filling is not necessary, and shellacking will prepare it for any of the finest polishes.

Oak.—Oak is the “King of woods", and is very useful. It consists of grains of wood and must always be filled before shellacking. Almost any sort of polish may be used for finishing oak, one of the most beautiful and the “grain filler” formula which has already been given. The linseed oil polishing will also make an excellent and durable finish. There is but one objection to this finish for wood apparatus, which has made it unjustly unpopular, and that is that the acid in the water and the wood have a peculiar effect upon hard rubber panels.

Mahogany.—If expense were not an objection in most cases, mahogany would be an ideal wood for every purpose. It is coarse grained, requiring a filler, but is sus-
Let Us Tell You How To Make a Big Success in CHIROPRACTIC

Advanced Science of Spinal Adjustment

Mail the coupon below, right now—today—and let us tell you all about the remarkable opportunities there are for ambitious men and women in this great, new profession of Chiropractic.

You are, of course, aware that drugless healing is steadily advancing in public favor. Chiropractic has come to the front so rapidly during the past few years that it is today recognized as the most advanced, most scientific, and most successful of drugless healing methods. It is calling to its ranks men and women from every walk of life—and there is abundant evidence that they are making good in a big way in this new and uncrowded field.

Mail the coupon and we will send you full information—tell you how there is a splendid chance for you to build a successful career as a Doctor of Chiropractic.

Learn At Home In Spare Time

The American University method of teaching Chiropractic enables you to study by mail or in class and obtain a complete education in the shortest time consistent with thoroughness, while you hold your present position. And you can pay on easy terms. A splendid faculty will personally instruct you in the basic principles and in the most approved methods for relieving Headache, Indigestion, Lumbago, Epilepsy, Pleurisy, Constipation, Rheumatism, Asthma, Neuralgia, Neuritis, Catarrh, Fevers, Jaundice, Dyspepsia, Paralysis, etc. No special preliminary study is needed. You will graduate with the degree of Doctor of Chiropractic, receive a handsome diploma and be ready at once to open your office.

$3,000 To $5,000 a Year

There are many instances of Chiropractors earning from $3,000 to $5,000 a year. Some upwards of $10,000. Dr. M. D. Moore, of Kentucky, reports an income of $8,000 a year. Dr. J. H. Roche, New Jersey, $5,000; Dr. Hanna, of Florida, over $5,000 yearly. The success of Chiropractors in many cases has come so quickly as to be almost startling—almost like the accidental discovery of a gold mine. And yet, it is not to be wondered at when you consider the scientific accuracy of Chiropractic methods, the really remarkable results of a beneficial character in the treatment of both acute and chronic cases that have been affected through these methods, the rapid increase in the number of people who have a decided preference for Chiropractic over any other treatment for their bodily ills and the comparatively few Chiropractors that are now in the field.

Remarkable Free Charts Offer

We want men and women seriously intending to take up professional careers in Drugless Healing to have these charts. Their actual value is $11.50. But on our offer they come free. There are 22 in all, printed in colors. Send the coupon below to get all the facts about our offer.

- Anatomical and Physiological Charts (with bound Manuel Key). Hand-colored Lithographed in Life-like Colors.
- Original Compendiaries.
- 5 Illustrated Spinal Columns.
- Colored Nerve, Pain Area and Concussion Charts.
- Magnificent Charts—Value $11.50—all Absolutely FREE.

Your Opportunity

If others have achieved such remarkable successes is there any reason why you should not do as well or even better?

Why not get out of the rut and qualify now for this splendid profession that offers such remarkable possibilities for making you prosperous and independent? No matter where you live, if you are ambitious to make money, increase your social standing and be a 'somebody' in the world, our course in Chiropractic will point the way for the attainment of your ambition. Never has there been a more opportune time than now. For never has the demand for competent Doctors of Chiropractic been so great as it is today.

SEND

the coupon today. Don't delay. Do not think that your chances for building a successful career are less than others who are succeeding in the practice of this great profession. Just let us give you all the facts—and judge for yourself. Mailing the coupon places you under no obligation of any kind whatever. We ask the opportunity to prove to you that what we tell you is the absolute truth. We have the facts to prove it—facts which you will find mighty interesting. Just send the coupon or post card for our beautiful new illustrated 72-page book and full particulars of our remarkable Free Charts Offer. Mail coupon or write today SURE.

CORE WIRE

(Continued from page 810)

certible of a fine polish, which makes it much in demand.

Maple.—Hard maple is close grained and requires no filler, but soft maple is just the opposite, and hence it is of little value. It looks best in its natural color, very light, which is preferably obtained by the use of white shellac and the very whitest ivory varnish—be found. Hard maple takes the finest polish of any of the woods.

Black Walnut.—This is a dark-colored wood, rather open grained, requiring a filler to make its color, but a good one. One good coat of orange shellac will suffice to level its surface previous to polishing.

Pine, Poplar, etc.—These soft woods are open grained and easily worked. Having little beauty of their own they are usually stained, but we should remember that oil stains are the best to use, owing to the difficulty of getting an even coat. Shellac will do very well as a varnish for these soft woods, being applied on top of a liquid filler.

In conclusion it is to be hoped that anyone attempting to do wood finishing will do the work justice and conscientiously perform all the operations required. Everyone has preferences as to the finish liked best, but after a study of the foregoing it should not be difficult to select the right one.

FORMER KAISER CONSTANTLY IN TOUCH WITH BERLIN

The former Kaiser is believed to be constantly in communication with Germany. It is reported that a wireless station has been erected on top of Count von Ber- tinch’s castle, and that German airplanes frequently fly over the estate, dropping messages.

SCIENCE IN SLANG

(Continued from page 799)

that it was the inherent what-you-may-call-it in the deceased animal and not the contact of the two dissimilar metals on the nerve and muscle, and the chemical action created thereof, that caused the insensible corpse to do the post-mortem Hula.

“Even at that the Dago doctor opened up a lot of dope that the terrestrians were dead to, and laid another foundation next for the next of the scientific gang to add to. And now we have galvanic current instead of homoeo, as would be the case had the blind ditty writer pulled the stunt.

“And then Count Professor Allesandro Volta, B. S., enlightened himself with Couronne de Tasses (no, not demi-tasses) and plates, and condensing electrosopes, not to speak of the other heterogeneous paraphernalia that would make a Hebrew junk dealer itch in the palms. Well, Aleck stamped his cognomen in the pages of electrical history, as well as on fuse plugs and such other electrical stuff that has the potential inscribed on it.

“Here comes along Andre Marie Ampère and drops the aching public a string of facts tabulating a stack of laws governing the flow of the ‘juice’ and propounding with such effect that we now wilt into the store and order the fuses that we shot—or rather to replace the ones we shot—and then the ampere (unless we bought them by the dozen).

“So it goes. Watt then bounces into the limelight and does his act and exit. Then, when they are sure he is dead, some favoring girl—usually a Prof.—takes some thing after him. In this case it happened to be the great what-is-it. So, too, we get ohms and farads—see; Mike’s handle was too long for laboratory use so the printers just stuck in the first half dozen characters and let it go at that. Likewise we amputated...
Learn Public Speaking
10 LESSONS FREE

Write — quick — for particulars of this extraordinary offer; an opportunity you will never forget if you take advantage of it. Ten lessons in effective public speaking absolutely FREE to those who act promptly, to introduce our course in localities where it is not already known.

We teach you by mail to become a powerful and convincing speaker — to influence and dominate the decisions of one man or an audience of a thousand. We have trained hundreds and helped them to increase their earnings and their popularity. Learn, in your spare time at home, how to overcome "stage fright" and conquer fear of others; how to enlarge your vocabulary; how to develop self-confidence and the qualities of leadership; how to RULE others by the power of your voice alone; how to train your memory. Our

WHAT THE COURSE TEACHES YOU.
How to talk before your club or lodge;
How to address board meetings;
How to propose and respond to toasts;
How to make a political speech;
How to tell entertaining stories;
How to make after-dinner speeches;
How to converse interestingly;
How to write better letters;
How to sell more goods;
How to train your memory;
How to enlarge your vocabulary;
How to develop self-confidence;
How to acquire a winning personality;
How to strengthen your will power and ambition;
How to become a clear, accurate thinker;
How to develop your power of concentration;
How to be the master of any situation.

New Easy Method

perfection and taught only by Prof. R. E. Pattison Kline, former Dean of the Public Speaking Department of the Columbia College of Expression, can be learned in 15 minutes a day. Prof. Kline is one of the foremost authorities in the country on public speaking and mental development. Do not let this chance escape you.

...
CUT YOUR OWN HAIR

If you can COMB your hair, you can CUT your own hair with this marvelous invention. You can cut your hair any length you desire, short or long, and finish the job as nicely as any barber in one-fourth the time before your own mirror, with the

UTILITY Hair Cutter

You can keep your hair well trimmed for a lifetime with this marvelous invention for actually any length of hair. Every good barber would charge you for a single hair cut. Very easy to manipulate. Use it just like a comb, pushing it through the hair, downward in the direction the hair lies. It is impossible to leave any "nicks" or "cut steps" in your hair, as there is a special Guard that guides the cutter blade evenly over the scalp.

Cut Children's Hair

at home and save time, trouble and expense of taking them to the barber shop. Works so easily and the job is done so quick that the children have no hair cut. The adjustment feature, whereby the blade can be set to cut the hair to any desired length—short, medium, or long—makes it possible to do a perfect work as the barber, not to mention the tremendous saving.

As a Safety Razor

You can use the Utility Trimmer as an ordinary Safety Razor, and it will give you a good shave as the most expensive razor you can buy. 
You can shave the face or neck, or around the temples.

EASY TO HONE AND STOP BLADES

No trouble at all to keep the blades sharp. Just reverse the blade in the holder and proceed to stop it with an ordinary razor. Extra Blades are always available and cost only 5 cents each, or 25 cents the dozen.

USEFUL FOR MANY OTHER PURPOSES

There are many other uses for the Utility Cutter that will suggest themselves to you. 
Ladies use it for removing hair from the arms and elsewhere. It is perfectly safe, and cannot cut the skin.
One customer wrote us that he found it just the thing for cutting corns, while housewives and tailors say there is nothing better for it—its cut, and making buttonholes.

AGENTS AND DEALERS GET OUR PROPOSITION

This is one of the rare occasions when you are asked to come up with a proposition to sell on Retail, with no cost, no risk, no extra expense. You will have the opportunity to make a better profit than you ever did with a similar product. We will supply you with all the literature you need, we will make you a liberal profit.

ELECTRICAL EXPERIMENTER

March, 1919

line, along comes a lot of other by-product stuff. A load of new hypotheses and another load of theories to explain them. You know when you hook up some plants in parallel that there enters into the circuit a condition known as 'harmonics' that jiggles the peak around and cuts it off, and goes negative when the generators are trying to make a positive impression on the line. Alternating current is great stuff and the guy that hits on it in the first place is far ahead of the man who stands on the wimpy ground of the direct. Steinmetz has this alternating current stuff pretty well under his hat and can tell you just what will happen, and when and why. If you ask 'Stemy' how he figures it he will tell you with a paper and pencil—if he did not do it in his head; but when the figures run ten into one or two hundred he generally reaches for his pencil. With his calculus he calculates the two-stepping oscillatory currents correctly thru his heavy cigs.

"Surely we all know what Tommy Edi-son has done to us in the line of sidewalks and phonographs, in stock tickers and electric plugs on street railways and chemistry.

That old duck works overtime seven days to the week and sleeps with his hat and shoes on, with a copy of Clerk Maxwell's dictionary for a pillow. Yes, Tom is a bright boy.

To-day, after all the headlights and sidewalk signs on history, we know more or less, but and less of, the so-called 'electric' force that causes our incandescent globes to glow and the amber to attract pitch balls than our propertizers who wore fig leaves and bed-spreads.

Perhaps some day a man—maybe a woman will come along and kick the mud out from the electrical puddle and let us see what a 'wait' really is. At least we will find more things that the mysterious force is the cause of. We may add a new mental, static, dynamic and other present forms we have so far classified yet more. 
High frequency may be the way to it—it may. But I realize that we merely collect or cause to flow in our set paths the 'juice' we use, we do not create it. In a way we are only considerably crudely in the field of electricity.

A lot escapes us, a lot leaks, as it were, and we get the use of a very small amount for the work we put into it and get out of it. Yet it is the most efficient forms of energy that we now have at our disposal. Perhaps some one will stumble on something other than dynamos and batteries for our support. It may be a sort of collector or electric acumulator. Thru electricity we may over-come taxation, that sort of a thing that would make possible are unlimited. Of course, that is supposition, but 'wireless' and the World War were all suppositions a few years ago.

'Speaking of wireless, Hertz looked over our heads and saw something we had overlooked since Galvani's 'return shock' on the frog's hind legs.

Then Marconi and others, notably De Forest, boosted the proposition along, so that now, with the audion amplifier, we transmit music, both chim and instrumental, for miles and miles on thin ether. Whether next we will transmit or merely collect energy for power I don't know, but I would not be surprised at either.

'Some scientists tell us that once our present planet was a whirling mass of molten globular mass. It came into existence via a gaseous state. As these cooled they formed rings or films surrounding the earth. Later these rings descended upon the earth, periodically. Thus the earth was thru the Paleozoic and Carboniferous.
ELECTRICAL

How I Increased My Earnings From $2 to $200 a Day!

The Remarkable Story of a Young Man’s Experience
After Reading a Wonderful Book, as Told by Himself

SOME people say it takes money to make money—others complain that they never made money because they never had any luck. When one is up against the stern reality of making both ends meet, it is natural to feel that if they only had a little money, or a little luck, they wouldn’t have to worry about their bread and butter, and rent, and clothes.

A short time ago I, too, felt that way. I was a bill clerk earning only $12 a week, and I used to worry myself sick about my future.

To-day—it seems like a dream—all my financial troubles are over—my weekly income is about $1,000—more than I know how to spend. I have two automobiles and have a chauffeur to drive me around.

My children go to private schools. I have just purchased, for cash, a $25,000 home. I go fishing, motoring and traveling, whenever I care to. I live in a new kind of world.

Possible to Anyone

Let me say in all sincerity that what I have done, I believe my own, that anyone of you can never tell when that ring may fall.

What You Can Do

I have been authorized by the publishers of Prof. Haddock’s methods to say that any reader who cares to examine his startling book on will power may do so without sending any money in advance. In other words, if after a week’s reading you do not feel that “Power of Will” is worth $3, the sum asked, return it and you will owe nothing. When you receive your copy for examination you will be interested in the studies on The law of great thinking; How to develop analytical power; How to guard against errors in thought; How to drive from the mind unwholesome thoughts; How to develop fearlessness; How to use the mind in handwriting; How to strengthen personality, and hundreds of other similar personal power studies.

It is a fact that among the 250,000 owners of “Power of Will” are such prominent men as Judge Ben B. Lindsey; Supreme Court Justice Parker; Will Tong Pang, ex-U. S. Chinese Ambassador; Senator T. B. Calon; Gov. McKelvey of Nebraska; Assistant Postmaster-General Brit; General Manager Chratsen of the Wels Line; Col. Clino Lewis; Senator Arthur Capper of Kansas, and thousands of equal prominence.

I am a firm believer that one of our greatest weaknesses would suggest immediate action in this matter before you. Use the blank form below, or write a letter addressing it to the Felton Publishing Company, 307 Wilcox Block, Meriden, Conn., and the book will come by return mail. This one act may mean the turning point of your life, as it has meant to me and to so many others.

FELTON PUBLISHING COMPANY,
307 Wilcox Block, Meriden, Conn.

I will examine a copy of “Power of Will” at your risk. I agree to remit $3 or return the book in 5 days.

Announcement

The Moorhead Laboratories, the largest exclusive manufacturers of Vacuum Valves in the world, have been busily engaged during the war in supplying Vacuum Tubes to the British and United States Governments.

They will have manufactured and tested a large quantity of these Vacuum Bulbs to meet the requirements of the amateur and experimental trade as soon as the ban is lifted.

All these Valves are licensed under the

FLEMING PATENT

owned by the Marconi Company, and protected by several pending patents.

We are the distributing agents of the Moorhead Laboratories, and you can obtain from us the same high grade Detector, built to Government specifications and supplied to the above mentioned Governments as standard equipment.

We will give you the most prompt and satisfactory service that it is possible to render.

Send your name and address to us, and we will forward you an interesting booklet describing the Moorhead Valves and other Apparatus for both receiving and transmitting.

Yours for efficiency

Pacific Laboratories Sales Department
510 PACIFIC BUILDING
San Francisco, Calif.
Gigantic 1,400 K.W. Radio Station at Lyons, France

(Continued from page 791)

work, it having been found readily possible to synchronize two such high-speed radio frequences at the works of the General Electric Company, some years ago.

North of the main antenna switch platform, at the station where the large, French design of static frequency multiplying system rated at 150 K.W. This set operates on the principle of the transformer frequency-changing principle, as developed by Joly and Arco.

Next we come to the western wing of the station, and here are two of the largest motor-generators ever built. They were designed by Mr. C. F. Elwell, formerly Chief Engineer of the Federal Telegraph Co., San Francisco, who first developed the Ponsan arc system to large powers, and each of these gigantic arcs are rated at 250 K.W. Either of these arc generators may be connected to the antenna thru the central antenna switch gear, the lead wire running to the arc apparatus, and on a massive single-pole, double-throw change-over switch, about five feet in length, which permits the instant connection of either set to the antenna.

Either of these powerful arc sets can be operated from the 300-K.W., 750-volt, direct-current motor-generator set, shown in the figure, or fed directly, without any use of the arc apparatus itself. This motor-generator comprises a three-phase, alternating-current motor, driven by a direct-current, 300-K.W. generator, which supplies the necessary high voltage direct current for operating the arcs. Dr. de Forest states that, in his opinion, these large arc generators represent one of the very finest developments in radio transmitters, that have yet been conceived, or perfected. They have a distinct advantage over frequency alternators in that quick changes in wave length or frequency can be rapidly obtained, merely by changing the inductance and capacity in the oscillatory circuits connected to the arc itself. The radio frequency alternator is very reliable, and development in this line has been a very rapid and reliable manner, but it is difficult, at least with the present design of this machine, to obtain and maintain a sufficiently accurate, changeable change in the range of wave lengths and frequency, yet as Dr. de Forest has intimated, they are very efficient and desirable where you turn your attention to the wave lengths available, as such where but one or two wave lengths only are desired. The arc apparatus is, of course, very simple and rugged in design, and requires but very little attention, even when operated over twenty-four-hour non-stop periods, which is the case in many of the Government stations which are using arc sets, and many of which are in very successful operation in some of the larger stations of the United States as well as in Europe at the present time.

All of the transmitters at the Lyons station, as the reader will perceive from the antenna frequency values given above, and the undamped wave system is used in all except the spark sets. The receiving apparatus is very elaborate, and has been installed in sound-proof receiving rooms, so as to realize the highest degree in the necessity of long distance signals. The French radio engineers are using nothing but three electrode audions in all of their work, and one of the finest sets is illustrated and described in the April issue. The French receiving sets make use of two or more amplifiers, and it is necessary to a six-stage amplifier is used, which boosts the strength of signal received 1,000,000 times. Some of the clever work accomplished by the French Army and Navy radio experts during the war, with these powerful audion amplifiers can readily be imagined, and it is a matter of record that many valuable radio as well as regular telegraph and telephonic wire messages were sent out, and that these were taken by the French stations equipped with these powerful amplifiers.

The power for the Lyons radio station is transmitted for a long distance from a hydro-electric plant. The receiving apparatus was built by the Compagnie Generale Radiotelegraphique, situated at Paris. The detector is, of course, the French type of audion. They employ a six-step audion amplifier, using the same standard bulb both for detecting and amplifying.

The ground connection of the station consists of a large number of copper wires radiating from the station and buried about two miles (650 feet) below the surface of the earth. Many of these wires terminate in copper plates.

HOW I INVENTED THE AUDION.

(Continued from page 790)

pleation was not filed until the following February, as shown in Figs. 2 and 6, of this patent show the incandescent or glow lamps members both in the air, and sealed within a closed enclosure.

It will be noted now that I approached the general problem of this new type of detector from an entirely different angle from that commonly supposed to-day. In the first place I always employed a battery, and this original battery was what is now universally called the "B" battery. My source of electric current for heating purposes was second, and secondary, so that the vociferous contention of the advocates of the Fleming valve and the tube detectors for the Fleming valve, and was originally the Fleming valve with the "B" battery added as an afterthought, is but a trifle.

It was now a very obvious development of the evolution thus far described, to partially exhaust the glass envelope containing the two incandescent electrodes, or filaments, so as to increase the conductivity of the space between them.

But the real value of this patent, showing the inclosed filament and glow lamp bulb, is interesting from another consideration because it contains the first embryonic germ of the later audion and cathode-ray tube. It was realized from the very first that a certain proportion of the high frequency energy from the antenna could be lost thru the bypath circuit connecting the audion and telephonic receiver. In order to prevent this the arrangement shown in Fig. 5 was tried out, wherein the local and high frequency circuits are kept separate. In this arrangement, as actually tried in the gas flame, no actual advantage was observed, because the high frequency electrodes were necessarily some slight distance from the path conducting the direct current, and hence the effect of the high frequency currents upon the ions carrying the local current was weakened.

During the years of 1904 and '05 my duties kept me almost continually away from my laboratory, in travelling about the country directing the installation of numerous radio stations; consequently there was little opportunity for carrying on this development work, and carrying out the designs and sketches which I made from time to time. It was not until 1905 that a lamp manufacturer was found to under-take the construction of the various experimental forms of lamps which I had designed as a successor to the flame or arc detector, I was familiar in 1905 with Prof. Fleming's work on the subject of the "Edi-
ELECTRICAL EXPERIMENTER

March, 1919

Super-Sensitive Microphone

This instrument is offered at an extremely low price. It is excellent for building your own amplifier. It can also be used in many experiments where a sensitive microphone is required.

Detectograph, $15

This detecting instrument of various sensitivity may be used for detecting secret conversations. It consists of a Super-Sensitive Transmitter with coil connecting. It is manufactured in pairs and is sold for $15.00 each. One pair is sufficient for a small room or a large one.

WIRELESS TELEGRAPHY

Our 14 weeks course prepares you for MERCHANDISE

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
In the spring and summer of 1906 I had opportunity to spend a good deal of time on the audion problem, and was always seeking to improve its efficiency. Keeping in mind then the disadvantage of directly connecting the high frequency circuit with the local circuits, and harking back to the four electrode gas-flame detector above mentioned, I sought to keep one electrode of the high frequency circuit distinct from the two electrodes of the local current. Obviously the most simple experiment was to wrap a piece of tinfoil around the outside of the glass bulb and connect this to one end of the secondary transformer of my receiver. The other end of the transformer was connected to the filament, it being obviously unnecessary to employ four electrodes to effect the end desired. Exactly this arrangement, with the third electrode around the outside of the bulb, is shown in Fig. 3 of patent No. 841,366, which was filed in August, 1906. It will probably be recalled that this outside electrode has been very recently "re-discovered" with considerable eclat and acclaim! I also at this time wrapped a coil of wire around the bulb, connecting one end of this to the antenna and the other to the ground, seeking thus to exercise an electrostatic condition in the inner electrodes by electro-magnetic influence from the high frequency oscillations passing around this helix. See Fig. 4, patent No. 841,366.

The arrangement of the external tinfoil belt may therefore be called the parent of the third electrode. It showed a decided improvement in the sensitiveness of the detector, as I had anticipated. I recognized that by this arrangement I had in effect a condenser between the filament connection and a hypothetical third electrode, which consisted of the conducting layer of gas located on the interior walls of the bulb, the other arm of this condenser being the tinfoil belt outside the glass. I recognized also that this was a very inefficient and indirect way of impressing the effect of the high frequency oscillations upon the conducting medium between the filament and plate. The third electrode should therefore be placed inside the bulb. I immediately instructed McCandless & Company to make such a bulb. The first type of this third electrode was in the form of a plate, located on the opposite side of the filament from the "B" battery plate. This arrangement showed an increased efficiency and sensitiveness anticipated. It is shown in Figs. 2 and 4 of patent No. 841,387, filed October, 1906. This is the audion amplifier and telephone relay patent. Fig. 2 of this patent is interesting as showing also for the first time a third battery ("B") in the external circuit between the third electrode and the filament. T in this figure represents the high frequency transformer.

In Fig. 4, where this battery is omitted, it is shown for the first time the grid stopping condenser C. In studying this type of three electrode bulb, I recognized that the third electrode was not yet in its most efficient position. It should be placed directly in the path of the ionic or thermionic stream, passing from filament to plate, where the high frequency electric charges impinge on the electrode could best affect this stream. But if placed directly between two electrodes, a solid plate, of course, would constitute practically a complete barrier. Hence I devised the grid or perforated screen structure. In fact, the first audion where the third electrode was placed between the filament and plate utilized the wire bent in grid form which is familiar to every amateur or user of the audion prior to 1914, to which third electrode so located was so marked an improvement over the preceding three-electrode bulb, that shortly thereafter a patent was applied for on it. This was issued in February, 1908, No. 879,532. See Fig. 1 where the complete receiving arrangement and the grid audion is clearly shown.
The audion remained in this form for six years. During that time its merits became gradually recognized in Europe as well as here, and it was not long before the little stranger was, like its predecessor, the two electrode brother with "B" battery, adopted into the Marconi family, and its predecessor rechristened the "Fleming Valve". As soon as the audion amplifier had been developed for long distance telephone service by the engineers of the Western Electric Company, and installed on most of the long distance lines of the A. T. & T. Co., we find certain English publications adopting it also into the Fleming valve family; and now after the three-electrode device has demonstrated its utility as a radio transmitter of absolutely constant undamped waves and made possible transoceanic telephone, we learn that this big brother which I first named the Oscillion, is also to the Fleming valve. The term "junior" or "senior" is used to distinguish one from the other in this rapidly growing Fleming valve family.

The art founded on the three-electrode audion has grown of late years with enormous strides. The great war has produced a tremendous intensity of development for various military purposes and it cannot be disputed that the engineers of the Western Electric Company were in a foremost position, and much of the present-day efficiency of the detector and amplifier has been due to their efforts, spurred on as they were by the difficult demands and specifications of our Signal Corps officers and engineers. It is estimated that there has been constructed for the U. S. Signal Corps during the war between 240,000 and 300,000 audion and amplifier tubes, and at least 50,000 small oscillators. In Great Britain war-time production has probably equalled or exceeded the goal. While in France we are informed that during the last two years of the war, the audion production has averaged about 5,000 per month! The French bulk is particularly interesting as being efficient and suitable in all three uses, detector, amplifier and oscillator. For such purposes, of course, a compromise in efficiency was inevitable, and maximum efficiency in either of these three branches has been somewhat sacrificed.

Considerable discussion has lately arisen as to the first use of the audion as an oscillator or source of alternating current. This matter is now being thrashed out in a multiple interference procedure in the U. S. Patent Office. But the evidence so far indicates that the writer's application of this property of the audion in the spring of 1916 should be the first use of the audion as a generator of undamped electrical currents. In view of recent developments, particularly the highly interesting announcements of President Vail of the A. T. & T. Co., regarding multiplex wire telephony and telegraphy over a single conductor pair, it may be prophesied that the application of the audion as a generator of alternating currents will be fully as useful as that of detector and amplifier.

There is, in the writer's opinion, no doubt but that if the development of radio is not now made a Government monopoly, it will not be long before commercial trans-oceanic wireless telephony will be effected. This work, whether the generator be a bank of oscillators or a high frequency alternator, will be made possible only by the extraordinary amplifying properties of the audion, when used as telephone repeater or relay. The simplicity of the oscillation transmitter in small sizes, coupled with the extraor-dinary sensitivity of the "zero beat" audion detector or amplifier of received high frequency energy, warrants the belief (Continued on page 531)
the nineteen-set of meters dial is an instantaneously photographed film. When the meter-reader gives back to the office, the exposed roll film is removed from the camera and the roll inserted. The film is then developed and the bills made out from the record photographed thereon.

Down on the farm we find another interesting light, the Uncle Josh will swear that the old barn lantern is much better, and this is in the testing of eggs for fertility. Several attachments have been produced, or one can easily be made from a piece of cardboard, aluminum or tin, in the shape shown in the accompaniment, Fig. 7, so that a strong beam of light is thrown against the egg, as it is placed in the opening in the candle screen. In connection with it it is interesting to note that by holding a flashlight bulb against the hand or against the finger that it is possible to locate foreign bodies in the finger. The illumination is very intense, and will act almost like an X-ray.

Figure eight shows a doctor's hand lamp fitted up in an emergency or for regular use as a flashlight. The battery is connected with a piece of flexible tinfoil to the lamp bulb, which is preferably mounted in a cardboard envelope secured to a piece of fiber, and which in turn is wired or sewed to a strip of elastic webbing. A small buckle can be secured to the free end of the webbing, so as to hold it in place on the head in any desired position. A polished nickel reflector is held in place by the lamp when screwed into the socket, as illustrated.

Another clever use for flashlights is in the form of a deep signal, and this scheme is so light that it has been tried out with great success in several offices. A diagram is given for a three-wire return call system. The beauty of the flashlight call is that it is not given to any nervous person a shock to the ordinary buzzer or bell, and it is also very simple and cheap to install. Any one can install such a signal system in a few minutes' time. Ordinary bell wire or some flexible lamp cord is used for connecting the two stations. The internal connections made to the flashlight battery are clearly shown in the diagram. Where two or more flashlights are used on one desk, the lenses may be of different colors, so that the patty calling is indicated more quickly.

Figure ten shows one form of electric clocklight. Of course, most ordinary mortals find the pocket flashlight very useful about the bedroom, and invariably keep one under the bed, so that it is only necessary to flash it on the clock or watch and ascertain the time whenever desired, but in some instances it proves more convenient or desirable to have the lamp bulb mounted on the clock base as here shown. Those desiring to utilize this scheme can easily arrange what is necessary is the ordinary flashlight, the proper length of flexible tinfoil and a push-button, preferably of one kind and variety.

Figure eleven illustrates one out of about ten thousand possibilities in electric flashlight advertising and tie-in novelties. The illuminated "Stove pipe" and shirt box shown, were not merely sketched by the artist, but were actually used for several years in New York City, and tickled the heart of the younger set well before they grew up. The man fitted with this illuminated silk hat and shirt bosom was quite a hit on Broadway at one time, and created one of the most novel surprises progressive advertising ever initiated. Needless to say, the best results are obtained with such an arrangement when the lights are flashed on and off at short intervals. In the present case the hat became illuminated first and then the shirt bosom, the arrow in the front of the hat sign causing the onlooker to glance downward invariably, and at that psychological moment, lo and behold! the shirt boson blazed forth in its red-and-white-striped glory, to the effect that "Killian's" whisky was the only stuff that had the "punch"—it didn't say it was a deadly punch, to be sure.

The illustration at Fig. 12, shows a very ingenious and most useful instrument utilizing the flashlight principle and known as the "inspectoscope." As the illustration shows, the inspectscope comprises a tube either of fact length, or else made telescopic, at the lower end of which there is a mirror inclined 45 degrees, while at the upper end of the tube a small flashlight case and its battery are mounted. The lamp on the tube receives current thru the metal tube, and the other side of the circuit is completed thru a single insulated wire leading up to the flashlight battery, the button switch on the battery case being used to light the lamp. This instrument has been found extremely useful in reading name-plates on motors and other machinery where they happen to be in inaccessible locations, such as close to a wall, etc. Many other practical and ingenious uses of the flashlight will suggest themselves to the reader, and it is doubtful if there has ever been any one invention in the electrical field that has become more universally adapted than the pocket flashlight.

POPULAR ASTRONOMY.

(Continued from page 781)

the planet is best seen. Its flattening at the poles, which is nearly ten per cent of its equatorial diameter gives it a decidedly oval appearance. Ordinarily one of the hemispheres of Saturn is partly or entirely concealed by the rings so that the oblate form is not noticeable. After the time shown on the diagram the rings in 1920 the earth will pass from a position below the rings to one above them. The northern hemisphere of the earth and the northern hemisphere of Saturn will come more and more into view after this date, the southern surface of the rings being invisible and the southern hemisphere of the planet being seen until the rings once more approach their widest opening or maximum separation. From this time on until the earth is once more in the plane of the rings, after another quarter revolution of the planet, the elevation of the rings above the earth becomes less and less and the width of the system decreases in proportion to its length. It was this change in the tilt and visibility of the rings that so perplexed Galileo when he attempted to make out the nature of the appendages of Saturn with his crude telescope of insufficient magnifying power. So great was his bewilderment when the rings finally disappeared that he cried out in despair that Saturn must have swallowed his children—another Jesuit legend. He finally became so exasperated with the results of his observations that he gave up observation of the true nature of these appendages of Saturn and remained a mystery until Huygens solved the problem in 1655, some time after the death of Galileo.

In addition to the rings, Saturn has nine satellites named in the order of their distance outward from the planet: Mimas, Enceladus, Tethys, Calypso, Rhea, Titan, Hyperion, Iapetus and Phoebe. The last mentioned satellite was discovered by W. H. Pickering in 1918 with great interest at the time because it was the first satellite to be discovered with "retraged" motion in its orbit. Two satellites of Jupiter since discovered revolve in the same direction around their primary. The satellites of Saturn approximate to

(Continued on page 823)
THE SKINDERVIKEN TRANSMITTER BUTTON presents the latest advance in microphones and marks a revolution in transmitter construction. It works on an entirely new principle, takes up practically no room, and marks the end of all telephone transmitter troubles.

The SKINDERVIKEN TRANSMITTER BUTTON can be placed in any position and it will talk loudly and distinctly and is at the same time extraordinarily sensitive. It was primarily designed to replace the old damaged or burnt-out transmitter. Simply unscrew and remove the telephone transmitter front, disconnect the two inside wires, unscrew and remove the bridge and the old electrode. There remains only the diafram. These wires are then connected with the Skinderviken button, the latter screwed to the diafram, and after screwing the old transmitter housing together again, the telephone is ready for work.

ELECTRICAL EXPERIMENTER readers will be particularly interested in all the different experiments that can be performed with the Skinderviken Button. Fig. 1 shows the Skinderviken button attached to the back of an Ingersoll watch case. When speaking towards the inside of the case, it will be found that the voice is reproduced clearly and loudly.

$1.00 prepaid This shows how button is attached to ordinary telephone transmitter.

Fig. 2 shows another interesting stunt. By attaching the button to a tin diafram about the size of half a dollar, and by holding the diafram at the side of the throat, as shown, speech can be transmitted with surprising clarity. Fig. 3 illustrates the same arrangement placed on the chest as shown. In this position the transmitter will talk clearly and loudly. Fig. 4 shows an arrangement whereby the Skinderviken button is attached on a thin wood board at the preacher's pulpit. His voice is clearly transmitted so that people hard of hearing can readily hear the sermon. Fig. 5 shows how a very sensitive Detectophone can be made by placing one of the buttons in the center of a lithographed cardboard picture, so that only the small brass nut shows. The large surface of the picture acts as a big diafram, and the voice is well reproduced. Fig. 6 shows an interesting stunt, whereby a hole is drilled in the side of a thin glass water-tumbler; the sides of the glass thus acting as a diafram, the voice is clearly transmitted. Fig. 7 shows a simple match box Detectophone. The Skinderviken button is concealed inside of the box, only the small brass nut showing on the outside. This device talks well. Fig. 8 shows how to transmit phonograph music at a distance merely by drilling a small hole in the phonograph arm and attaching the Skinderviken button: a very favorite experiment with all experimenters.

We have such unlimited confidence in the Skinderviken Transmitter Button that we make the following remarkable offer. Send us one dollar ($1.00) for which we will mail one button prepaid. If you do not wish to keep it, return it within five days and your money will be refunded. Boys! send stamp for booklet No. 4. It gives diagrams and experiments using the Skinderviken Transmitter Button, and prices of telephone equipment.

ALSO ALL KINDS OF TELEPHONE PARTS FOR EXPERIMENTERS at prices far below the actual cost of manufacture.

Sirs:

Examination of the satellites of Jupiter can be easily found that they are not as interesting to observe as the satellites of Jupiter because they are on the average four, hundred million miles more distant.

The time they require to make one journey around Saturn varies from nearly twenty-three hours for Mimas, the nearest, to approximately five hundred and twenty-four days for Phoebe, the most distant.

Like Jupiter, Saturn is marked by belts parallel to its equator but they appear more indistinct than those of Jupiter on account of the greater distance of Saturn. Saturn also resembles Jupiter in its physical composition which is largely, if not entirely, gaseous and in the extremely short period of rotation on its axis which is approximately ten hours.

In more ways than one, Saturn is a very unusual planet. In addition to possessing an enormous ring system it is the lightest of all the planets, its density being only three hundred times that of water, and it is the most oblate, or flattening at the poles alternating nearly to one-tenth of its diameter. Its equator is more highly inclined to its orbit than is the case with any other planet, not even excluding the earth's axis to Mars. For this reason its seasons are very great, in marked contrast to Jupiter whose equator lies very nearly in the plane of its orbit. Since Saturn is so far away from the sun that it receives only one-nineteenth as much light and heat per unit area as the earth, its outer gaseous surface must be extremely cold unless considerable heat is conveyed to the surface from within its hot interior.

Prof. Lowell concluded from certain observations made at Flagstaff, Ariz., that Saturn is composed of layers of different densities and that the inner layers are more flattened at the poles and rotate faster than the outer layers. Marked variations in the color and brightness of the ball of the planet have been noted from time to time. In 1833 the planet was described as pinkish-brown and consequently darker than the brighter portions of the rings and it may be said to have been found in the constellation of Leo not far from the star Regulus at the end of the handle of "The Sickle." It is more than twenty years since the planet was noticed in any other pinkish tint. As it was in opposition to the sun on February 14, it is now most favorably placed for observation, being visible all thr sun.

EXPERIMENTERS!

A Sample of What You Can Do With This Outfit

This illustration, made from an actual photograph, shows only a very few of the instruments that can be made with the Electro Electric Toys:

**ELECTRIC DRAWING INSTRUMENTS.**

Permission does not permit to show the hundreds of other experiments that can be done with this outfit.

The outfit contains 144 separate pieces of material and 24 pieces of finished articles ready to use in electrical work.

Among the finished material the following parts are included:

- Chrome snails for battery, lamp socket, bottle of mercury, core wire (two different lengths), a bottle of iron filings, three spoons of wire, carbons, a quantity of machine screws, flexible cord, two wood bases, glass plate, paraffin plate, binding posts, screw-driver, etc., etc.

The instruction book is so clear that anyone can make the apparatus with but little trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the layman with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The price of all the outfit is Electro $5.00. Shipping weight is 8 lbs. No. EX2002 "The Boy's Electric Toys" outfit as described.

**IMMEDIATE SHIPMENTS.**

The Electro Radiophone.

**MICR FREQUENCY SILENT TEST CALL BOX**

This instrument gives a wonderful high pitched musical note at the receivers, which can be stopped by any ordinary testing instrument. The RADIOPHONE is a built-in, high-class telephone, the transmitter being a sandwich of two thin copper wire screens vibrating at a remarkable high speed, adjusted to give the highest frequency at the factory. The instrument is very sensitive, and the effective frequency may be increased by moving the two screens. The receiver is of the highest quality.

You will be astonished at the wonderful clarity of the 500 cycle note, sounding exactly as if you were receiving a two-way conversation, such as a personal note. With the radiophone, you and one dry cell and any telephone, a letter is sent back. You need only three or four notes to end the thrill.

Price Complete: $1.25. Shipping weight: 2 lbs.

**IMMEDIATE SHIPMENTS.**

The Electro} Telegraph.

A bit of electricity, but not a practical instrument. The Codophone Codophone is made of brass and does not work as well as the Electro Codophone Codophone.

**WHAT THIS REMARKABLE INSTRUMENT IS**

Used as described, the Codophone Codophone is a talking telephone, sending and receiving messages, and does not work as well as the Electro Codophone Codophone.

Price Complete: $1.50. Shipping weight: 2 lbs.

Can YOU Honestly Ask
Any Girl To Marry You?

CAN you marry any girl, without making her the victim of the meanest kind of deceit a man is capable of? Are you fit to be a husband, fit to make the girl you love the mother of children who will inherit your traits of body and mind? Think, and think hard, before you give her your body and soul into her keeping, unless you are FIT. You know what the Law of Heredity is—there's no beating it; what YOU are when you become a father your children ARE bound to be.

Make Yourself Fit to Be a Father

If you are skinny, undeveloped, weak, watery-blooded, build yourself up before you marry, so your children will not be rickety imitations of yourself. If you are dyspeptic, bilious, constipated, or the victim of any other chronic ailment, such as youthful errors, vital losses and consequent impotency, get rid of these handicaps; don't take the risk of passing them on, in exaggerated form, to the helpless little children you will bring into the world. You can't commit a worse CRIME than to make a weak, puny, unattractive mother the mother of weak, puny, unattractive children, and a blessing to you and to the girl you marry. No matter how low down you have got in the human scale, and no matter how low you are, YOU CAN COME BACK, if you go about it the right way.

I don't care how much druggist's dope or patent pilfe you may have tried without success; three hundred years ago the greatest brain in England wrote "Throw Physics to the Dogs"—and Shakespeare knew, as every doctor knows today, that physic isn't the kind of food that makes men strong and vital, that fills them full of overflowing life and energy and spirit.

Get Strong in Nature's Way

Give old Mother Nature a chance to cure your ailments and build you up, by living in the way she meant you to live, and you'll be amazed in a few weeks' time at the improvement in your health. If you are skeptical about it, there's no doubt about what she can do for you; and there isn't any other way: Nature's way is the ONLY way many men on the ragged edge of being thrown into the everlasting scrapheap of humanity can EVER get back the health and strength and virile vitality and manhood that make man.

I KNOW: I've tried it, not only on myself—and I am called the strongest man in the world today—but also on thousands of miserably ailing, weak, decrepit, discouraged men, and other troubles, that are the result of these ailments. I have always found that the best way to gain health and strength is through Strongforton that I teach. I will help YOU, as I have helped them, and as I am helping other men in every quarter of the civilized world today, to develop your muscles, reanimate your vital organs, steady your nerves, ease your heart, increase your brain; how to become, in a short time, a 100 per cent Man and take the place in the world you ought to hold.

Send for My Free Book

I have put the results of my life's study, research and experimentation on the subject of man's vitality and vigor into a book called "Promotion and Conservation of Health, Strength and Mental Energy." It will tell you all about Strongforton, show you how thousands of men who had lost their grip were able to become red-blooded, vigorous citizens again, and point out the way—the simple, easy, natural, quick way in which YOU can gain and retain health and strength and the ability to enjoy life, and those 2 stamps to save postage and packing and I will mail a copy to your address at once.

cupy a range between the frequencies of the ordinary telephone currents, which are those of the human voice, and the lowest frequencies which are used in wireless communication. This frequency range has not herefore been commercially used. It is interesting to note that under favorable conditions the whole range is audible to many and the lower part of the range is audible to any one with normal hearing. It is found that frequencies within this range are high enough to be used as "carriers" of ordinary telephone currents and yet with proper arrangements can be transmitted over long telephone lines without the large transmission losses and large interference between circuits which would be brought in by lower frequencies.

Each additional circuit in the new system makes use of some frequency within this range. At the sending end of each circuit, the ordinary telephone current is made to modulate this "carrier" frequency by means of an audion tube so that the unmodulated carrier frequency sent out on the line varies with the amplitude of the ordinary telephone currents. At the receiving end the carrier current is put into a demodulating circuit, which includes another audion, and which then gives out the original telephone current.

The different circuits are kept separate at each end by inserting in each circuit a combination of impedances which make up an electrical "filter." This transmits the range of frequencies passing through each circuit and stops all other frequencies. An important difference should be noted here between this system and wire systems in which wireless working is done. It has been generally sufficient to send and receive in "tuned" circuits. In the multiplex system, however, tuned circuits would not be sufficient since each telephone channel occupies a range of frequencies of about 2,500 cycles and any circuit tuned to these comparatively low frequencies would be too "selective" to receive such a range in the proper manner.

Vacuum tubes (audions) are used in the modulating and demodulating circuits and are also used as amplifiers in the transmitting and receiving branches and at intermediate points along the line where necessary to prevent the currents from becoming too highly attenuated.

In regard to the increased telegraphic capacity afforded, Mr. C. C. Harbison states:

"The advantages of the system when applied to telegraphy as well as to telephony were clearly shown in tests. We found that we can combine our system with the printing telegraph so as to secure the full advantages of the latter and the full advantage of the modulated multiplex system in reducing wire requirements. Using our multiplex system with the ordinary hand operated telegraph instrument, connected with a telephone circuit, we can send from 1,500 to 2,000 words in a minute. When the multiplex system is connected with the printing telegraph, we can send, from 4,000 to 5,000 words in 60 seconds."

GOLD AND SILVER LOCATED WITH SOUND WAVES.

(Continued from page 769)

the ore bodies. For example, if the distance between the record made on the oscillograph, R-D, by the triangulation on depressing the key K, and the record made by the arrival of the sound directly along the line Q, which would be the first sound to return after the depression of the key, is five inches—then one inch on the photographic record corresponds to one mile in distance, since drill hole R is located six miles from the key. D. This establishes the standard of measurement on the oscillograph.

Now for example, if the length between the key depression record and the record made at D, by the sound reflected at P is...
9 inches, it is evident that the sound proceeding from O and reflected at P, and finally reaching the point Q, had traveled 9 inches. Again, the length between the key depression record on the oscillograph, R—O, and the record made by the sound sent out from O, and reflected back from the bottom Fig. 2, is a 9 inches, then it follows that the ether body 1, is located approximately 4 miles from the point O. The error in this measurement of the intersection of the sphere described about O, with a radius of 4 miles, with the sphere described about D, with a radius 9 miles, is 1, i.e., 5 miles.

There are a number of ways outlined in Prof. Fessenden's description of his invention, which may be utilized for locating the exact point on the line of intersection where the ore bodies are located. As he points out, it is possible to find this point of intersection mathematically, if the angle deflection between the key depression record and the echo record made by reflection, say at J, Fig. 4, together with a determination of the direction of the sound received, which employs two of his oscillators connected together, separately. This scheme of locating ore deposits may sound a little hazy or improbable at first glance, but the theory, can be readily tried out by means of a small siren and a receiver or two, together with some auxiliary apparatus which any electrical experimenter can readily devise, the difference in such an experiment being that the waves are not reflected or refracted in air, but in applying this system to the location of buried ore deposits, the sound waves travel through rock and soil as well as water, in which mediums the velocities of sound propagation varies considerably. The velocity of sound propagation through water is about four times as great as that through air, or approximately 1,100 feet per second for air and 4,700 feet per second for water.

BOOK REVIEW.
(Continued from page 801)

This work is the official reference and study manual used by all naval men. The various operations of the navy, the details of a naval life are described and illustrated. This work contains the daily life of the navy, specially described and suitably illustrated. The reader is thus able to learn the life of a ship's crew and understand the duties of each rank. The work is written in an easy manner, and is published so that by reference to the special indexes given in the book, the reader can locate certain sections of the text concerning the ship, the crew, the work of the ship's officers, etc. The work is a valuable guide for those interested in the navy.

The Free Trial Offer for 7 days examination, shipment charges collect. I will examine the books thoroughly, and if satisfied, will send them to you for 7 days on approval. If you decide not to keep them, you may return them to me at your expense. The offer is only good for 7 days and is subject to the amount of sent money remaining open for purchase.

Special Offer

To those who mail this coupon promptly we will send you a free year's membership in the American Technical Society with every set of books.

This will enable you to consult our engineers and experts on any subject of mutual concern. It is the policy of our society to maintain the highest ethical standards and to promote the development of science and technology. We believe in the free exchange of ideas and the cooperation of all who are interested in the advancement of knowledge.

AMERICAN TECHNICAL SOCIETY
Dept. X-3333, Chicago, III.

See the Free Trial offer below and mail the coupon for one of these pay-raising sets of books. They are written by some of the greatest experts in each line and tell everything you need to know to make you an expert and give you a better job.

Plain everyday English, pictures, diagrams, plans, etc., make difficult things simple as A-B-C.

Thousands of men have made these books, and are making more money. Hundreds are sending for every day. You can do it too. Pick out the set that suits your own work best and send for it for a week's free trial.

Carpentry and Contracting

Books cover the entire field of carpentry and contracting, including stonework, masonry, plumbing, carpentry, and more. The books are written by experienced carpenters and are illustrated with diagrams. The regular price, $25.00, special price, $18.00.

Telephony and Telegraphy

Books cover the entire field of telephony and telegraphy, including the principles of the telephone and telegraph, the construction of telephones and telegraph apparatus, and the operation of telephones and telegraphs. The books are written by experienced telephonists and are illustrated with diagrams. The regular price, $25.00, special price, $18.00.

Steam and Gas Engineering

Books cover the entire field of steam and gas engineering, including the principles of steam and gas, the construction of steam and gas apparatus, and the operation of steam and gas apparatus. The books are written by experienced steam and gas engineers and are illustrated with diagrams. The regular price, $25.00, special price, $18.00.

Sanitary, Heating, and Ventilating Engineering

Books cover the entire field of sanitary, heating, and ventilating engineering, including the principles of sanitary, heating, and ventilating, the construction of sanitary, heating, and ventilating apparatus, and the operation of sanitary, heating, and ventilating apparatus. The books are written by experienced sanitary, heating, and ventilating engineers and are illustrated with diagrams. The regular price, $25.00, special price, $18.00.

Accountancy and Business Management

Books cover the entire field of accountancy and business management, including the principles of accountancy and business management, the construction of accountancy and business management apparatus, and the operation of accountancy and business management apparatus. The books are written by experienced accountants and business managers and are illustrated with diagrams. The regular price, $25.00, special price, $18.00.

Machinery and Architectural Drawing

Books cover the entire field of machinery and architectural drawing, including the principles of machinery and architectural drawing, the construction of machinery and architectural drawing apparatus, and the operation of machinery and architectural drawing apparatus. The books are written by experienced machinery and architectural draftsmen and are illustrated with diagrams. The regular price, $25.00, special price, $18.00.

Wireless Taught By Mail

Merchant Marine Needs THOUSANDS of Operators

Men also needed for big Land Wireless Stations—Aerial Mail Service—Railroad and Telegraph companies. Salaries up to $250 a month. Excellent opportunities to win promotion to Radio Engineer—Inspector—or mechanic. Chance to travel the world over or locate at Land Station in America.

Complete Course by Mail in Ten Weeks

Our students actually pass commercial examination in Real Work or less. Start studying NOW in spare time at home. We send you Complete Set Practice Examinations for receiving and sending messages, while studying our course. We help you secure position in any branch of Commercial or Government Radio Service. Write TODAY for Free Pamphlet. A postal will do it.

NATIONAL RADIO INSTITUTE
Dept. 70
Washington, D. C.

ACCEPT THESE BOOKS FREE

Since we published these two books, over 8,000 of each have been sold. If you are a wireless experimenter, you can ill afford to be without these two latest authoritative works, published by the one concern in America that knows what the "How-to-make-it Fiend" really wants. In these two hand books are concentrated the most important, up-to-date wireless instruments and directions how to make them. They are by far the most successful wireless books of the season. Size of each book is 5x7 inches, substantially bound on a good book paper. The covers are in two colors. We really can not praise these works too highly. You will be delighted with them.

EXPERIMENTER PUB. CO., 233 Fulton St., New York

Gentlemen:

On your absolute guarantee that your two big Wireless Handbooks are just as described by you, you may send me same FREE. All charges prepaid. You are to send me these books at once, and enter my name for a full year's subscription to the Electrical Experimenter, 12 numbers, for which I enclose $2.00, the price of the Electrical Experimenter alone.

"THE NATIONAL AUTHORITY ON ELECTRIC WIRING FOR TWENTY-FIVE YEARS"

ALL YOU NEED TO KNOW ABOUT WIRING

IS IN THE LATEST EDITION OF

"STANDARD WIRING"

This year's edition, completely revised to date, is the only accurate book on electric light and power wiring and construction published. The National Electrical Code, with all its new rules, is explained and illustrated. 52 of the latest and simplest tables which show, at a glance, just what size of wire is needed for any kind and size of lighting or motor installation, for any voltage, current and drop desired for any system, single, two or three-phase. The latest Code Rules on grounding required on all work.

How to install and operate generators, motors and every kind of wiring device with diagrams of connections, Special chapters on Illumination, House Wiring, Electrical Units and their Equivalents. The latest lamp data. Proper symbols to use to indicate outlets, etc., etc.

It Will Make You an Expert Wireman

Leather Cover - Pocket Size - 375 Pages - Price $1.50

SEND TO ANY ADDRESS, POSTPAID, ON RECEIPT OF PRICE

H. C. CUSHING, Jr. 8 West 40th St. NEW YORK

The layman will find in this book all kinds of information concerning naval affairs such as the different sizes and mountings of naval guns, how and what ropes are used for, including the tying of all kinds of rope knots, discussion on modern battleships, and other very useful and practical drawings thru the various decks, details concerning pay of enlisted men and officers, also procedure in the matter of enlistments, discharges and court martial, small arms such as the automatic pistol and high power rifles, etc. Other sections deal with the handling of small boats, sails, signals of all kinds, deck seamanship, the compass, log and lead, marching formations, artillery marks, mines, etc. The signal flags for the international code, etc., are printed in colors. The book is well printed and bound, and proves a very good reference volume on the complete detail of naval discipline and all of the operations connected with the handling of naval affairs.

HOW I INVENTED THE AUDION.
(Continued from page 820)

that before long the wireless telephone will be installed on thousands of vessels, supplementing, and in many cases, supplanting the wireless telegraph. In addition there is an enormous number of small vessels where a wireless telephone installation is more feasible.

As indicative of the growth of the Audion Art, a number of patents issued on various devices and circuits dependent thereon, gives a pretty fair key: Up to 1912 there had been issued about 20 patents, all filed subsequent to 1904. To-day there are over 100 United States patents on the Audion Art, and the number is very rapidly growing. It is not the intent of this paper to review all the work that may be applied to the device patented, practically everyone of these patents since 1906 shows the three electrode bulbs. They may all, however, be properly described as the outgrowth of the ideas first shown in the audion amplifier—patent No. 841,887.

EXPERIMENTAL CHEMISTRY.
(Continued from page 794)

cuprous oxide, or gold; Yellolowish-green, by uranium oxide; Green, by chromic or cupric oxide; red, by ferric oxide; white, by manganese dioxide; and black, by manganous oxide. The green color of the common window glass or bottle glass is caused by the presence of ferrous oxide in the sand; this decoloration may be removed by addition of manganese dioxide in the make-up. This is done by adding a green copper oxide, which imparts a yellow tint, being neutralized by the violet produced by the manganese as a complimentary color.

Pure white is produced when the metallic oxides required, in the proportion which experience has shown gives the best result, but a small amount of "cuttle" is added to improve the quality. The mixture is then put into pots as shown in Fig. 159. These pots are made of the most insulating materials and placed in a circular furnace with openings thru which the workman can dip his long iron blowpipe into the pots. Fig. 160 shows such a furnace in cross-section.

The fuel now used is mostly gaseous, and an intense heat is maintained for hours, till the substances are completely fused and mixed. The glass worker dips his blowpipe—a hollow iron rod 5 or 6 feet long, into the fused mass, removes a small portion, rolls it on a smooth iron

THE ROGERS UNDERGROUND - WIRELESS.

(Continued from page 789)

The illustrations and materials in all the tests and installations made of my underground radio system thru all the trials and testing of its development, even when the system seemed to prove unworkable. Their perseverance and high skill in the radio art has hastened the official recognition and the installation of the buried and submerged antenna.

Commander A. Hoyt Taylor, D.Sc., U. S. N.; Dr. E. H. Haswell, Bureau of Standards; Admiral Strother Smith, U. S. N.; Commander Hooper, U. S. N.; G. H. Clark, Expert Radio Aid, U. S. N.; Dr. George W. Taylor, Harvard University; and Ensign A. Crossley, U. S. N., who has been actively engaged on the installation of the Rogers system at the Great Lakes Naval Radio Station besides New Orleans, New London, Conn., (test station, now abandoned), and Norfolk, Va.

Like many inventions the exact mode of operation is hard to ascertain and define. The views of Mr. Rogers on the operation of this wireless system are briefly described as follows—First, that the electric energy liberated at the base of an antenna will be propagated thru the earth even in the absence of etheric space waves above it, and second, that the electric energy propagated in all directions is the cause of the electric phenomena observed in the real world. The latter is a new and important discovery which is of tremendous importance in electrician practice, industry, and research.

CARNOTITE

(Rodium Mineral). The American Pitchblende found in Colorado, from which Radium is extracted.

A generous niece, enough to conduct experiments, with all the necessary apparatus, plates of rare metal and rare apparatus,

URANIUM

for our booklet No. 4, giving diagrams and experiments with the Stego Electric Generator and the Auto-Wheel.

INSIDE SPORTS Inner Armour

An excellent article on wave electricity and wave apparatus. Really useful in your life! American Accessories Co., Dept. 65, Cincinnati.
These ground currents travel with the speed of light and are picked up at the receiving station. The space waves persist for an appreciable distance, which accounts for the ability of air-plane and air-plane-to-earth radio-communication, but it is the belief of Mr. Rogers that in such long distance radio transmission at half-way around the globe (12,000 miles) that it is the ground wave current that does the work, and that the free space wave above the surface of the earth never reaches the station due to the high resistance of the atmospheric envelope.

One of the Naval experts present mentioned that it has been found, that the penetration of the ground wave component increases with an increase in wave length. This is an important fact and helps to explain the operation of this new radio system, with its aérais buried in the ground. He also mentioned that "Radio to Mars" or other planets would be impossible, if we are to believe in the well-known "Heaviside" ionization layer, surrounding the earth at a height of 30 to 50 miles, for no etheric wave can pass this layer without being reflected back to the earth, or at least restrained within this passage-way.

Rogers System Eliminates "Static" and "Interference".

Mr. Rogers stated that his underground antenna, in itself, did not solve entirely the static or interference problem, but it made the nearest approach to this ideal condition—the goal of all radio engineers—that had ever been accomplished before. This problem has, thanks to a new arrangement perfected by Commander A. H. Taylor, D.Sc., been solved and static and interference have been practically totally eliminated, for all year-around radio service. Think what an advancement this is! Further, there is no rise and fall in the signal strength during the night or day, at any time of year, so that the sun's ionization effect, as is the case where elevated antennas are employed. The U. S. Naval reports and tests made with the Rogers' ground aérais in comparison with the usual form of elevated aérais, several of which are appended hereafter, show the incomparable efficiency of this new radio system.

What The Facts Show.

First we will mention the test which Mr. Rogers and a naval officer conducted for the writer. The apparatus used in these tests is shown in the accompanying photographs. They included several large tuning inductances, variable condensers, a step-up audion amplifier (single Audion bulb only!) and two pairs of Baldwin phones (telephone receivers). This apparatus was connected up to one of Mr. Rogers' latest buried antennas—a single rubber covered, stranded copper cable, about the size of a small ignition cable, extending westward for a distance of 4,000 feet, so as to be in a plane with the high power European radio stations. This cable is buried in trench 20 foot wide by 20 foot by 20 foot, 10 feet deep, consisting of about 3 feet deep, filled in with soil. The cable is insulated at the free end and is connected up as in Fig. 2. The rubber covered wire alone has been in use in all sub-aquatic tests, and gives fine results when simply buried in the ground, the decay not being so rapid as probably would be imagined. This latest aerial in the iron pipe is a new development and experiments are in progress on it. It works wonderfully well. The 4,000 foot aérial here described is best suited to receiving wave length of 6,000 to 16,000 meters. For short waves longer aerials of smaller dimensions are employed.

You can TREAT YOURSELF at home with the wonderful Violet Ray, most effective health-restoring agent known to science. At practically no cost, the great benefits of famous Violet Ray Treatment herefore only procurable at big expense from physicans and beauty specialists, now secured in your own home. Look over the list of treatments on the coupon below. Send for particulars.
ELECTRICAL EXPERIMENTER
March, 1919

"Here's the 'Lyons' station in France," said Mr. Rogers. A turn of the knob on the specially calibrated condenser, and there was "Lyons" (France)—satisfactory enough. Static and interference were unheard. Next the great stations across the broad Atlantic at New York, Washington, Car-

Avenue, England; and Rome, Italy, were heard with equal loudness and clarity. This laboratory station, which has been used by the Navy Department during the war, has picked up practically all the high power stations on the globe. American stations were then picked up by changing the wave length, and finally a station made on a short (250 feet in length) buried ground antenna, adapted to receiving wave lengths of 200 to 800 meters. Wireless telephone messages were picked up from Washington, a distance of about seven miles. It is most interesting to note at this juncture, as the Naval tests at Norfolk, Va., on a similar aerial have shown, that a radio message from an airplane cannot be picked up on the underground aerial, until the 'plane is directly over the station. This would seem to prove two things—first, that the short waves sent out by the airplane do not penetrate down into the ground very far, if at all;—and second, that airplane radio transmission and reception are effected solely by etheric waves.

Referring to Fig. 3-A, 3-B, and 4, we have several interesting points. Fig. 3-A shows how a double ground aerial is sometimes connected. Also, as in the case of Mr. Rogers' test station, sets of these buried antennas are best employed, distributed about the station as shown in Fig. 3-B.

The Rogers underground antenna system has been used at New York, New Jersey, and during the war with most gratifying results, as reported by the Navy Department, and its successful operation during the twenty-four hours of the day, resulted in trebling and quadrupling the capacity of this great trans-Atlantic highway of intelligence communication. The official reports in connection with the work accomplished with the underground Rogers system at Delmar state that not a single word of communication was lost during the reception of thousands of important official messages from Europe. The station at Tuckerton, N. J., has also been equipped with the Rogers underground aerial system and all of the larger stations of the Allied Powers in Europe have been copied successfully thru the 24 hours, at this point also.

Submarine Wireless.

Perhaps the most interesting tests of all are those which were made on submerged aerials in salt water. The aerial in this case was of heavily insulated stranded cable, stretched from stem to stern as Fig. 4-A illustrates. The two ariels were brought down thru the counting tower and joined to the receiving apparatus. A second form of aerial is illustrated at Fig. 4-B, where the insulated aerial wires are placed in iron pipes within the submarine. Here are the results of some of these tests, which do not include the transmitting tests to the submarine from a grounded antenna on shore. When submerged 8 feet, the German station at Nauen was picked up by the submarine while lying off the American coast! Submarine tests, picked up distant stations when submerged 21 feet, on a wave length of 12,500 meters or greater.

One of the naval officers, who has had much to do with the testing of the Rogers' system, stated that experience had demonstrated the fact that even submerged antennas may be placed at any depth. Salt water acts differently, but the aerial may be submerged any desired depth for wave lengths above 10,000 meters.

The same officer, who has made a close study of all American and European work in radio, explained how the best work ever done in radio was accomplished at the Great Lakes Naval Station, on the shore of Lake Michigan. Fig. 5 gives the general arrangement of this station. The test station was on the beach and acted as a "remote control" station for the standard station at A. The shortest distance between a 'receiving and control station for the radio service heretofore has been 36 miles. Here a distance of 600 feet only, separate the elevated aerial of the main station from the submerged Rogers antenna terminating at the test station, B. Said he, "Now let the inventors of 'static and interference preventers trot out their wares, and show what they can DO!" Here's what this station actually did on schedule service:

With 4 amplifiers, at 4,000 meters wave length, being radiated in the elevated main antenna—the beach station, ONLY 600 FEET AWAY, was picking up Nauen on 12,000 meters; and New Orleans on 5,000 meters, without any interference or static—all on the Rogers sub-aqueous ariels. These were rubber-covered cables spreading in different directions, any one of which could be used, and laying 50 feet deep in the water at their outer extremities.

Imagine such a wonderful performance! But this is not all. The official tests show that the station at Camp, P. I., 8,100 miles away, was received regularly on the Rogers sub-aqueous ariels at the Lake Michigan Station, on schedule service, at 11 A. M. and 5:30 P. M. daily, the working periods of that station.

Transmitting On Underground Aerials.

Tests were made by the naval experts, as well as by Mr. Rogers in his very first experiments in transmission from a ground or under-water antenna. These were all successful. It is only a matter of properly insulating the antenna so that it will not break down under the high potential applied to it by the transmitter. The early tests by the inventor were made with a one inch spark coil to the Bureau of Standards Radio Laboratory, a distance of seven miles, and the received signals having an audibility of 2,000, i.e., 2,000 times the strength of a clear, readable signal. The audibility of the signals at the Washington Navy Yard.

The Burgess BLUE BOOK for all practical Men and Electrical Students

(See review of this book by Editor in December issue of your Electrical Experimenter page 568)

I have prepared a pocket-size note book especially for the practical man and those who are taking up the study of electricity. It contains drawings and diagrams of electrical machinery and connections, over two hundred formulas for calculations, and problems worked out showing how the formulas are used. This data is taken from my personal note book, which was made while on different kinds of work, and I am sure it will be found of value to anyone engaged in the electrical business.

The drawings of connections for electrical apparatus include Motor Starting, How to Figure Weight of Wire, Wire Gauge Rules, Ohm's Law, Watt's Law, Information regarding Wire used for Electrical Purposes, Wire Calculations, Wiring Calculations, Illumination Calculations, Shunt Instruments, and How to Calculate Resistance of Shunts, Power Calculations, Efficient Calculations, Measuring Unknown Resistances, Dyna- mo and Dynamo Troubles, Motors and Motor Troubles, and Calculations of Transfer of Pulleys.

Also Alternating Current Calculations in finding Impedance, Reactance, Inductance, Frequency, Alternations, Speed of Alter- nators and Motors, Number of Poles in Alternators or Motors, Conductance, Susceptance, Admittance, Angle of Lag and Power Factor and formulas for use with Light Transformers.

The Burgess BLUE BOOK Will Be Shipped, Postpaid, on Receipt of $1.00
Order today—send dollar bill, money order or check. I guarantee satisfaction or will return your money if you decide not to keep the book after using it for five days.

ALEXANDER WIRELESS BILL IS KILLED.

(Continued from page 786)

today we are not at all excited even about the amendment of the Alexander Bill for we have good and sufficient reasons to believe that the Alexander Bill amended has little chance to become a law.

That our judgment was correct is borne out by the fact that the Bill was actually killed a month later. Many interesting things came to light during the hearings before Mr. Alexander in the latter part of April. Practical amateurs, small and large, professional and otherwise, had flocked to Washington to give testimony and to protest against the Bill. Many of the letters that Alexander received arrived in Washington, a flood of protest letters from amateurs had descended upon the national capital, and it was found that their services were not at all needed, for before their arrival several amendments had already been gotten up and were in print.

It is not our intention to belittle the genuine efforts made by these amateurs who went to Washington to fight for the cause, but we do not think that in the testimony given as published in the printed reports, anything new was shown or any new arguments. The committee had not been shown. Some other means were used to get the bill defeated, but we do think that the letter was not really what the applicants are trying for by the radio.

We guarantee you service to your employer as we guarantee our service to your employer. You can't Think will do it, Guaranteed service is simply the difference between "getting by" and GETTING ON. If you are only "getting by," if you aren't increasing your earning power, or if you can't guarantee your service, then you need and should get specialized training.

WE GUARANTEE

Our Training

Make no mistake about it! When we undertake to make you a skilled worker in your line of work, we absolutely guarantee to satisfy you in quality and thoroughness. Each course is conducted so that each student will see and learn the experiences of others, and experience helps us stand out from the rest of the world. We know how to make you a success, if you honor our service to you. You risk nothing by enrolling. You can't lose a cent. Our training will enable you to assure the employer service because of your training. That means to you in your position you want a chance to pay you in your position. This training lets you get more for your money. The training decides the pay.

Training Decides Pay

There's no question about it. You get paid for what you can do. That depends on what you know. Increase your knowledge with one of our courses. Let us prove your earning power increases accordingly.

You can travel at home in your spare time—backed by the assurance that we guarantee you service to your employer. You will not find a better training by enrolling than by enrolling at the American School of Correspondence. It is the only way to go. Try our Free Bulletin free of charge. Check and mail the coupon TODAY.

Thank you for believing the "Electrical Experimenter" when writing to advertisers.
amateur is concerned, and this is a good thing. We had maintained right along and we stated in our January and February issues, that no amendment nor new law was at all required. We had no suggestions to make, the old law was good enough, and we said so. When it was argued that it had to be amended, we were for the Paiget bill, which left the amateur just exactly where he was before the law was passed. Naturally we are glad to see that our judgment proved right, for official Washington thought so, too. The old law is good enough, it covers every possible possibility, and, we do not think that any legislator could do better than the Radio Act of 1912.

An interesting side light of the disturbed state of mind of the Department of War was the fact that Washington radio amateurs appeared to be their unanimous holy fear of the United States Navy. They all seemed to be absent, any, panic-struck that the Navy Department was at this the amateurs, which as a matter of fact, the Navy, speaking generally, was not.

We believe that our opinion is shared by those who know the inside facts, that the Alexander Bill as originally framed was a hasty measure, because at the time it probably was considered that private ownership for radio was rife, and that such a measure could be rushed through in haste.

The vacancies in our line make two fundamental mistakes: First, the country was and is not rife for public ownership as yet. Second, it was found that several hundred thousand American citizens, better known as Radio Amateurs, cannot be wiped off the earth by means of a blue pencil. Such methods might have had a small use before the war, but after what we have gone through in demobilizing the world and freedom for everybody, there is a great chance of the measure succeeding. Several senators and congressmen voiced their opinion on this point in no uncertain tones, and we are confident that at all events, a change will come up again during the next few years, which by the way we doubt, it will experience exactly the same fate.

Another mistake, which, however, is made by a great many people outside of Washington is that for some curious reason the amateurs at large has always been looked upon as a group upon which at any rate to put a stop. Even well informed Washington was greatly surprised to receive letters from "young" amateurs 60 and 70 years old, and these "boys" were not as a rule in any position when they were the young man of 20. Then the amateurs in uniform were legion, and their parents voiced their sons' sentiments, being that the sons themselves were perhaps in France or elsewhere. Further, the great hordes of amateurs known as jewelers made themselves heard lastly.

There are today thousands of jewelers located all over this broad land, whose business it is to serve their community by giving them just the right piece. They also regularly daily signals in their business. This time service was given free to them by Uncle Sam every day by the time signals sent out by Washington and other government stations. These amateurs under the original Alexander bill would have been killed right along with them same as their brethren who pursue wireless and other technical purposes, and you may be sure that these jewelers would have loudly in their complaints.

Our amateurs are to be congratulated in their solitary fight which they put up for their rights, and we congratulate them upon their victory.

There is, however, one serious point which we desire to broach, and that is the following:

When we first heard that a new wireless measure was to be rushed thru Congress,—which if it had actually past, would have killed wireless in the United States, we took it upon ourselves to broach the important news to every amateur on record.

The RADIO LEAGUE OF AMERICA, which was organized three years ago was formed for just such a purpose, viz., to keep the amateurs together and to ward off unfair legislation. Unfortunately, only about 20,000 amateurs had been registered with the League, altho it does not cost one cent to join the League. So when we came to write the letters to all the amateurs we knew, about 20,000 names were used, the others were made up from various lists which we had in our office, and which lists were not at all reliable on account of removals of amateurs, etc.

We wish to take this occasion to urge every amateur to fill out the blank printed at the end of this article and join the League at once. It does not cost a cent to do so except three-cent postage with which to mail this blank. You immediately become a member, and any important news can then be transmitted to you immediately without delay. It should be apparent to every amateur that being a member of the Radio League of America can only benefit him, and as much as there are no dues or fees to be paid, there is absolutely no good reason why every amateur should not be in it.

Perhaps he will soon be declared by the President and then everybody will be allowed again to operate his or their stations, and be a member in this well-established League, national scope and reputation can only benefit the owner of the radio station. Then, too, every amateur owes it to his Government to take part in a movement that will keep services can be drawn upon and his station used, and only by having a central body which has all such information can radio issues of the United States grow to its fullest and greatest importance.

Application for Membership in the Radio League of America

I, THE UNDERSIGNED, a Radio Amateur, am the owner of a Wireless Station. My station has been in use since

Radio League of America. I understand that the Radio League of America is a National Scientific Organization for the pursuit of the Radio Arts. I will not be called upon to pay membership fees, or dues, and once enrolled I am to share in all the privileges thereof.

Upon receipt of this form properly filled out you are to send me your eight-page booklet describing the purpose of the League, rules, etc.

Name:

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
ELECTRICAL station licensed bill was 837 one-half but amendment
You page by "Radio Governmenteries" Captain Lieutenant Committee
Editor, March, of Cooper
were amateur stations, and amateur stations, licensed as provided by the act to reg-
ulate radio communication, approved August thirteenth, nineteen hundred and twelve: Provided, That when such amateur stations are licensed for receiving purposes only no operator's license shall be required for the operator in charge of or operating such station; but when such amateur station is licensed for transmitting also the license shall require that the operator of such station shall hold a license showing his ability to send and receive at least twenty-five words per minute in the Continental Morse code: And further provided, That the license for such transmitting station may limit the power input to one-half kilowatt in case of amateur stations within one hundred miles of the Atlantic or Pacific Ocean, the Gulf of Mexico, the Great Lakes, and to one-quarter kilo-
wart within five miles of a Government receiving station. Amateur stations so licensed shall not use any wave length exceeding two hundred and fifty meters nor less than one hundred and fifty meters except by special authority in the license granted.

In order that the information given your readers may be correct, it is requested that you publish this letter in your March issue of the "Electrical Experimenters."

For your further information, there is being forwarded to you under separate cover a full printed copy of the Hearings before the Committee.

Very respectfully,
(Signed) E. B. WOODWORTH,
Commander, U. S. Navy,
Acting Director Naval Communications.

The amendment drafted by Lieutenant Cooper was scheduled to run in our Feb-

ruary issue. At the last moment, due to lack of space, it was crowded out. The amendment printed in our February issue was proposed by Mr. Watson as published by us.—Editor.

Editor, Electrical Experimenters,
233 Fulton Street,
New York, N. Y.

Sir:

It has been noted by this office that on page 707 of the February issue of the "Electrical Experimenters" you printed certain proposed amendments to a bill for Government Ownership of Radio Communic-
ation. On page 735 in an article entitled "Radio Amateurs Discussed Officially" you stated that this amendment was drafted by Lieutenant J. C. Cooper, Jr., U. S. N. R. F. You have evidently been misinformed. The amendment printed by you was not drafted by the Navy Department and was not dis-
cussed before the House Committee at the hearings.

The amendment actually drafted by Lieu-
tenant Cooper and discussed before the Committee appears in the testimony of Captain Todd on page 39 of the Official Report of the Hearings before the House Committee on Merchant Marine and Fish-
eries on H. R. 131, and is as follows:

"Insert after line 6, page 2, the follow-
ing:

"The term 'amateur station' means a station used for private practice or experiment in radio communication and not operated for profit in either receiving or sending radio signals.'

"Insert in line 14, page 3, after 'train-
ing-schools' the following: 'and amateur stations.'

"Strike out the sentence beginning in line 1, page 3, and ending in line 6, page 3, and in lieu thereof insert the following:

This section shall not apply to stations belonging to the Government of the United States or the Government of the Philippine Islands, or to experiment stations, technical and training-school stations, and amateur stations, licensed as provided by the act to regulate radio communication, approved August thirteenth, nineteen hundred and twelve: Provided, That when such amateur stations are licensed for receiving purposes only no operator's license shall be required for the operator in charge of or operating such station; but when such amateur station is licensed for transmitting also the license shall require that the operator of such station shall hold a license showing his ability to send and receive at least twenty-five words per minute in the Continental Morse code: And further provided, That the license for such transmitting station may limit the power input to one-half kilowatt in case of amateur stations within one hundred miles of the Atlantic or Pacific Ocean, the Gulf of Mexico, the Great Lakes, and to one-quarter kilowatt within five miles of a Government receiving station. Amateur stations so licensed shall not use any wave length exceeding two hundred and fifty meters nor less than one hundred and fifty meters except by special authority in the license granted."

MAKE MONEY REPAIRING TIRES

The high cost and limited supply of tires makes it necessary for motorists to conserve their tires and get maximum mileage. Present conditions offer tire repair men a big opportunity to make money. Experienced help not necessary.

With this Shaler Electric Vulcanizer you can make money easy. It heats from city electric light current —has automatic heat control—no danger of fire or explosions.

Will mend any style or size of tire—both casing and inner tube. Handles 12 casings and 200 tubes a day. Anybody can operate it, and turn out perfect work. Price $65.00 complete.

Subject to Trade Discount.

Write at once for catalog of our complete line of Shaler Vulcanizers, Steam or Electric for Repair Shops and quick selling models for motorists.

It contains the following 44 chemicals:

- Alum (Al(SO₄)₃, (NH₄)₂SO₄, Anhydrous (powdered) (Sn)
- Ammonium Aqua Oxide (NH₄OH)
- Ammonium Carbonate (NH₄₂CO₃)
- Ammonium Hydroxide (NH₄OH)
- Barium Chloride (BaCl₂)
- Boric Acid (H₃BO₃)
- Bromine (B₄O₇)
- Calcium Chloride (CaCl₂)
- Calcium Oxide (CaO)
- Calcium Phosphate (Ca₃(PO₄)₂)
- Carbon (C)
- Carbonate (CO₃²⁻)
- Charcoal (C)
- Chloride of Zinc (ZnCl₂)
- Copper Sulphate (CuSO₄)
- Ferrous Sulphate (FeSO₄)
- Ferrous Sulphide (FeS)
- Glycerol (Glycerine)
- Hydrochloric Acid (HCl)
- Iodine (I₂)
- Iron (Fe₂O₃)
- Lead (Pb)
- Magnesium Carbonate (MgCO₃)
- Manganese Dioxide (MnO₂)
- Mercury (Quicksilver) (Hg)
- Nickel Chloride (NiCl₂)
- Oxalic Acid (H₂C₂O₄)
- Sodium Bicarbonate (NaHCO₃)
- Sodium Bicarbo
- Sodium Carbonate (Na₂CO₃)
- Sodium Chloride (NaCl)
- Sodium Nitrate (NaNO₃)
- Sodium Phosphate (NaH₂PO₄)
- Sodium Sulphate (Na₂SO₄)
- Sodium Sulphide (Na₂S)
- Stannous Chloride (SnCl₂)
- Sulphate of Nickel (NiSO₄)
- Sulphate of Zinc (ZnSO₄)
- Sulphuric Acid (H₂SO₄)
- Tin (Granulated) (Sn)
- Zinc (Metal) (Zn)
- Zinc Carbonate (ZnCO₃)

The apparatus are furnished:

- One Standard Washbottle
- One Alcohol Lamp
- One Coupled Glass Measure
- One Erlenmeyer Flask
- One Glass Funnel
- One Delivery Tube
- Six Assorted Test-Tubes
- One Test-Tube Holder
- Ten Sheets of Filter Paper
- One Glass Dropper
- One Spoon Measure
- Glass Tubing
- One book containing Treatise on Elementary Chemistry and 100 Chemical Experiments be performed with this outfit.

**THE E. I. CO. CHEMICAL LABORATORY**

We present herewith to our friends our new E. I. Co. Chemical Laboratory which contains real chemicals and apparatus to perform real chemical experiments. This outfit is not a toy, but a practical laboratory set, with all the chemicals, apparatus and reagents necessary to perform real work and to teach the beginner all the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

**DESCRIPTION OF THE OUTFIT:**

The outfit consists of forty-four (44) Chemicals all C. P. (chemical pure) put up in appropriate wooden boxes, glass bottles, and hermetically closed jars. The acids are put up in glass bottles, with ground-in glass stoppers and there is a sufficient quantity of chemicals supplied (mostly one to two ounces) enough to make dozens of experiments with each. See list of Chemicals herewith.

The apparatus furnished are all of the best obtainable and of standard laboratory size and shape. A list of the 17 pieces of apparatus furnished with this outfit is printed also herewith.

The Instruction book is a real Chemistry Course for the Beginner.

Some of the contents are: Division of Matter: This is a Treatise on Elementary Chemistry and deals with the theory of the Elements, Molecules and Atoms, etc. Chemical Nomenclature. This explains in simple language the derivation of the chemical names of the Elements and their compounds.

There is a chapter on Laboratory Operations; Glass Working; First Aid; Fire Extinguishers; Experiments Aphorisms, etc.

A good part of the book is devoted to:

- Weights and Measures. The Metric System, the English system and the U. S. system are fully explained.

The following tables are furnished:

- Symbols and Atomic weights of the Elements.
- Measures of Weights, Volume, Capacity and Length.

Among the 100 Experiments are:

- How to make chemical tricks; How to make invisible and magic inks; How to test flour; How to test soil; How to make chlorine gas and smoke (German Gas); How to bleach cloth and flowers. How to produce oxygen and Hydrogen; How to make chemical colors; How to test Acids and Alkalis and hundreds of interesting hints and formulas.

Altogether all chemicals have nearly doubled in price, we have decided not to raise the price of this outfit for the present.

**The price is still $5.00**

THE ROGERS UNDERGROUND WIRELESS.

(Continued from page 835)

This "a sea at about 150 miles from New Orleans."

Main Antenna Underground Antenna (550 composite)

Sig 400 Static 5000 300 15

The "Aetherna" had been trying to get thru a naval despatch which could not be copied on elevated antenna on account of interference. This despatch was taken on the underground antenna, and every word copied correctly.

At 9 P.M., April 30, it was possible to copy signals from Tuckerton with ease, while static on the elevated antenna made it impossible to read any arc signals.

The following results were obtained with spark signals:

Three hundred foot wires in parallel, ten feet apart, a .002 m.f. condenser in series with primary coil of a 10kilocs receiver to obtain 600 meters.

Of particular interest is the fact that when static prevents reception on the elevated antenna, reception is continued on the underground antenna. This has been even done during a severe lightning storm, when the two stations had been rendered harmless without grounding. Reception is also directional and permits of avoiding interference to some extent by using wire off direction of station.

Strays: Strays are a rule practically absent. Occasional loud cracks widely separated are received. (Ed. note: such may not be overcome.) These isolated strays, alto frequent, do not interfere in the least with the reception of signals. On two occasions, strays have risen to an audibility in excess of 5,000 on these separate cracks, but even in this case, reception of signals, altho a little difficult, was not interrupted. Johnson says on these occasions it was necessary to ground both of the (elevated) aerals at the main station.

Considering the matter of strays, it can be said that on four or five occasions during one week, which was one marked by tremendous electrical storms, reception continued on the underground antenna, that strays rose to an audibility in excess of 10,000 at the beach station. Even in this case, however, signals from boats within 100 miles and from shore stations, such as Ludington, Milwaukee and Manitowoc, were usually readable, because the strays while very loud, were nowhere near as numerous as on the elevated aerial. During these periods a messenger was kept at the beach station to carry up messages to the main station as soon as these strays were not received these signals on account of the strays.

There seems to be no appreciable advantage in using more than one wire—No. 12 weather proof insulated.

The experiments at Great Lakes confirm the work of the Bureau of Standards on the importance of an adequate insulation of the wire. If the wires are grounded at the ends, it does not necessarily make much difference whether the wire is adjusted to the optimum wire length; but if properly adjusted to this length, grounding of the wires, either intentionally or accidentally, proves of little value to the stations, of which, however, even with the intentional grounding of the two ends, it leaves them 50% of their maximum value. Therefore, while the question of insulation is important, it does not mean that the system will fail entirely if the insulation becomes faulty.

cover. Suddenly my legs went up in the air. In the same instant there was a flash in my brain, the nerves responded, the muscles contracted, I swung thru 180 degrees and landed on my hands. I resumed my walk as tho nothing had happened when the stranger caught up with me. "How old are you?" he asked, surveying me critically. "Oh, Samson," I replied. "What of it?" "Well," said he, "I have seen a cat do this but never a man." About a month since I ordered new eyeglasses and went to an optician who put me thru the usual tests. He looks at me incredulously as I read off with ease the smallest print on the smallest distance. But when I told him that I was past sixty he gasped in astonishment. Friends of mine often grease that my eyes fit me like gloves but they do not know that all my clothing is made to measurements which were taken nearly 35 years ago and never changed. During this same period my weight has not varied one pound.

In this connection I may tell a funny story. Once everyone was in the wind of 1885. Mr. Edison, Edward H. Johnson, the President of the Edison Illuminating Company, Mr. Batchelder, Manager of the works, and myself boarded a lake boat opposite 65 Fifth Avenue where the offices of the company were located. Someone suggested guessing weights and I was induced to step on the scale. Edison got me all over and said: "Tesla weighs 152 lbs. to an ounce," and he guessed it exactly. Stript I weighed 142 lbs., and that is still my weigh. I whispered to Mr. Johnson: "How is it possible that Edison could guess my weight so closely?" "Well," said he, lowering his voice, "I will tell you one thing, but you must not say anything. He was em-ployed for a long time in a Chicago slaughter-house, and he is familiar with the hogs every day! That's why." My friend, the Hon. Chauncey M. Depew, tells of an Englishman on whom he sprang one of his original anecdotes and who listened with a puzzled expression but a year later—laughed out loud. I will frankly confess it took me longer than that to appreciate it.

Now, my well being is simply the result of a careful and measured mode of living and perhaps the most interesting thing is that three times in my youth I was rendered by illness a hopeless physical wreck and given up by physicians. More than this, three times, with all my good wishes, I got into all sorts of difficulties, dangers and scrapes from which I extricated myself as by a miracle. I was rescued from a thousand dangers and a dozen times; was nearly boiled alive and just mist being cremated. I was entombed, lost and frozen. I had hair-breadth escapes from certain death. I was more than once within a hair-breadth of being drowned a dozen times; was nearly boiled alive and just mist being cremated. I was entombed, lost and frozen. I had hair-breadth escapes from certain death. I was more than once within a hair-breadth of being drowned a dozen times; was nearly boiled alive and just mist being cremated.

I Train You by Mail!

Your spare time will do. No interference with your regular duties. I understand just what you must know and I have devised a wonderful way of instructing by mail. I positively guarantee your satisfaction.

I WILL MAKE YOU a Trained Electrician

I don't care how young or old you are, just as long as you can read and write and have a spark of ambition. I don't care where you live or what you do. I don't care if you don't know a blessed thing about electricity. Just give me a little of your spare time for a short period and I will teach you the beginning of electricity. You can qualify to earn $36 to $100 a week with opportunities for greater earnings.

LISTEN TO ME!

Be a CERTIFIED ELECTRICIAN

THIS IS YOUR CHANCE OF A LIFETIME

I am Chief Engineer of the great Chicago Engineering Works. I am in close official touch with the electrical world. I know how badly we need trained electricians who can take charge of important work as electricians. Right now there is a great need for executive electricians that I am making a special effort to help meet the demand. I am publishing this special announcement to secure a certain number of ambitious men whom I will personally train by mail for the wonderful opportunities that are open.

I WILL MAKE YOU a Trained Electrician

I don't care how young or old you are, just as long as you can read and write and have a spark of ambition. I don't care where you live or what you do. I don't care if you don't know a blessed thing about electricity. Just give me a little of your spare time for a short period and I will teach you the beginning of electricity. You can qualify to earn $36 to $100 a week with opportunities for greater earnings.

I Train You by Mail!

Your spare time will do. No interference with your regular duties. I understand just what you must know and I have devised a wonderful way of instructing by mail. I positively guarantee your satisfaction.

Free Wonderful Electrical Outfit

Absolutely free. Not a penny cost to you now or later. To those who act at once I will give a wonderful set of Electrical Equipment with my compliments. Write me at once. I have only a limited number of sets to be given free. Drop me a post card or letter.

Write! You will have to act quick to get in on this opportunity. Write me at once. I have only a limited number of sets to be given free. Drop me a post card or letter.

CHIEF ENGINEER COOKE,
Chicago Engineering Works,
Dept. 523
441 Cass Street, Chicago, Illinois
duck and I was confident that I could perform the feat. Accordingly I plunged into the water and, when out of view, turned around and proceeded rapidly towards the opposite side. Thinking that I was safely beyond the structure, I rose to the surface but to my dismay struck a beam. Of course, I quickly dived and forged along with rapid strokes until my breath was beginning to give out. Rising for the second time, my head came again in contact with a beam. Now I was beginning to panic. However, my mind was engaging all my energy, I made a third frantic attempt but the result was the same. The torture of suppurative breathing was getting unbearable—drowning and I felt myself sinking. At that moment, when my situation seemed absolutely hopeless, I experienced a stream of light and the structure above me disappeared before my vision. I either discerned or guessed that there was a little space between the surface of the water and the row of beams, and, with consciousness nearly gone, I floated up, press my mouth close to the planks and managed to inhale a little air. Unfortunately I was too late, a slip of water which nearly choked me. Several times I repeated this procedure as in a dream until, however, I was brought out at a terrible rate, quizzed down and I gained compound after that I made a number of unsuccessful dives, having completely lost the sense of reality until I succeeded in getting out of the trap when my friends had already given me up and were fishing for my body.

That bath had been spoiled for me throughout I must confess it was not before the lesson and only two years later I fell into a worse predicament. There was a large boulder with a dam across the river near the city where I was studying at that time. As a rule the height of the water was only two or three inches above the dam and to sweep a ten or twelve-foot board in the water was not so dangerous in which I often indulged. One day I went along the river to enjoy myself as usual. When I came to the instance of the dam, however, I was horrified to observe that the water had risen and was carrying me along swiftly. I tried to get up but I could not do so, for the current was too strong, I saved myself from being swept over by taking hold of the wall with both hands. The pressure against the wall was great and I was barely able to keep my head above the surface. No soul was in sight and my voice was lost in the roar of the fall. Slowly and slowly the water was which I was exhausted and unable to withstand the strain longer. Just as I was about to let go, to be dashed against the rocks below, I saw in a flash of light a familiar diagram illustrating the hydraulic principle that the pressure of a fluid in motion is proportionate to the area exposed, and that I turned on my left side. As if by magic the pressure was reduced and I found it comparatively easy in that position to resist the force of the water. The danger still confronted me. I knew that sooner or later I would be carried down, as it was not possible for any help to reach me in time. Then I attempted to slide to the other side and to rest and nothing remained but to slowly push my body along the dam. I had to get away from the dam and I was turned as the current there was much swifter and deeper. It was a long and painful ordeal and I came near to failing at its very end and with a depression in the manager. I managed to get over with the last ounce of my force and fell in a swoon. I reached the bank, where I was found. I had turned virtually all the skin from my left side and it took several weeks before the fever subsided and I was well. These are only two

**HEL-MET THE KAISER**

Send one to your boy in camp; all they want is only five cents. They will be shipped free. Germany should wear this pink, white, and green flag instead of the red, black, and gold. The Kaiser and his army can have no eyes or anywhere else. Hurl this book. A special edition of PUNCH is being published for the Kaiser, which will be circulated in Berlin, Munich, and London. Price 10 Cents.

**THE VENTRILOEU**

Is a little instrument that fits into the mouth out of sight. Boys or girls can use it. NEVER fail with the VENTRILOEU for TEN CENTS.

**NEW FORD JOKE BOOK 1919**

All the latest jokes and gags of a hundred, and all good ones. Spring a new one on your friends every day. By mail, 10c.

**Devil Resigns to the Kaiser**

Everyone who reads this book will wish that he had it. The Kaiser's Dream, A Letter from the Devil to the Kaiser, Kaiser's Prayer, How Satan Resigns to the Kaiser, etc. Many other stories, jokes, etc., about the German Emperor. Book mailed 10 cts. postpaid 2 cts extra.

**ROGEN X-RAY**

Price 10 Cents

This instrument apparently is what you want. It seems to be able to see through clothes, and see the heart. Send us the only one you can have with it. Sample by mail, TEN CENTS.

**SKULL RING**

This is a handsome, up-to-date token. It is not used as a flapper, but as a charm. Looks good and looks something frightful. And the one you won't like, best for men or boys (it is a great joke). It's only one. Sample by mail, 10c.

**Gee! What a Wad!**

This is STAGE MONEY. Looks like the GENUINE STUFF. Some Green backs and some old notes. Ready for use by the stage manager and any other field work. The girls will all be pleased with this. This take of 15 pieces by mail, 10c.

**Boys Own Toy Maker and Nine Other Books for 10c**

Tells you how to make a Telephone, a Magic Lantern, a Magic Slides, Electric Telephones, Auto Guns, and other wonderful and interesting things. This book with nine other interesting books mailed 10c.

**ENCHANTED BARREL**

The Most Wonderful Pocket Trick Made CHANGE A CENT INTO A DIME

Ask your friend to drop a dime in the barrel. Then take it out. He's 10c richer. You make it cents every time you fool him. Sample 10c by mail. Directly only.... 10c

Any three of the above articles for 25c or any six for 50c

**Royal Novelty Co.**

**ELECTRICAL EXPERIMENTER**
of many instances but they may be sufficient to show that had it not been for the inventor's instinct I would not have lived to tell this tale.

Interested people have often asked me how and when I began to invent. This I can only answer from my present recollection in the light of which the first attempt I recall was rather ambitious for it involved the invention of an apparatus and a method. In the former I was anticipated but the latter was original. It happened in this way. One of my playmates had come into the possession of a hook and fishing-tackle which created quite an excitement in the village, and the next morning all started out to catch frogs. I was left alone and deserted owing to a quarrel with this boy. I had never seen a real hook and pictured it as a glistening weapon endowed with peculiar qualities, and was desiring not to be one of the party. Urged by necessity, I somehow found a piece of wire, hammered the end to a sharp point between two stones, bent it into shape, and fastened it to a strong string. I then cut a rod, gathered some bait, and went down to the brook where there were frogs in abundance. But I could not catch any and was almost discouraged when it occurred to me to dilute the empty hook in front of a frog sitting on a stump. At first he collapsed but by and by his eyes bulged out and he bloodied, he swelled to twice his normal size and made a vicious snap at the hook. Immediately I pulled him up. I tried the same thing again and again and at length picked up the reputation of a supplier for my comrades, who, in spite of their fine outdoor had caught nothing, came to me they were duped with envy. For a long time I kept my secret and enjoyed the monopoly but finally yielded to the spirit of Christmas. Every boy could then do the same and the following summer brought disaster to the frogs.

In my next attempt I seem to have acted under the first instinctive impulse with later discovered may not have been to harness the energies of nature to the service of man. I did this thru the medium of May-bugs—rod and June-bugs as they are called in America—which were a veritable pest in that country and sometimes broke the branches of trees by the sheer weight of their bodies. The June-bugs were brought from the south but I would attach as many as four of them to a crosspiece, roatated with a thin spindle, and permit the motion of the same to a large disc and so derive considerable "power." These creatures were remarkably efficient, for once they were started they had no sense of stoppores continued whirling for hours and hours and the hotter it was the harder they worked.

All went well until a strange boy came to the place. He was the son of a retired officer in the Austrian Army. That urchin ate May-bugs alive and enjoyed them as tho they were the finest blue-point oysters. This disgusting sight terminated my endeavors in this promising field and I have never since been able to touch a May-bug or any other insect for that matter.

After that, I believe, I undertook to take apart and assemble the clocks of my grandfather. In the former operation I was always successful but often failed in the latter. So it came that he brought my work to a sudden halt in a manner not too delicate and it took thirty years before I tackled another clockwork again. Shortly thereafter I went into the manufacture of a kind of pop-gun which comprised a hollow tube, a piston, and two plugs of hemp. When firing the gun, the piston was prest against the stomach and the tuft was pushed back quickly with both hands. The air between the plugs was compressed and raised to high temperature and once of them was expelled with a loud report. The art consisted in selecting a tube of the proper taper from the hollow stalks which were (Continued on page 845)

Moving Picture Machine

A REAL moving picture machine that uses the same films as the big movie theaters all over the country and you can get it absolutely free with a box of film besides.

Have a movie show right in your own home. Entertain your friends and relatives. Charge admission and make easy spending money. You never had a chance like this before and it may not be repeated again. Send your name on the coupon NOW!

Boys! Girls! Act Quick!

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
He's Winning!

Because He Followed His BENT.

Age 28—Salary $2500 a year—General Manager of the Company—his own boss—owns his home—married and happy and prosperous—there's the success of Wal- lace H. Rohrshneider, General Manager and Secretary and Treasurer of the Hustisford Light, Power and Manufacturing Company of Hustisford, Wisconsin.

I followed my bent," says Mr. Rohrshneider. "That's all. I followed my bent. In these crisp words he sums up his success. Young—unknown—of humble birth—reared on the farm and deprived of scholastic advantages, he entered this school in 1907 and took up the study of Electricity. And today—at 28—in the work he felt he was fitted for—he's on the road to success. Simply because he answered his instincts. Simply because he followed his bent.

Is Electricity YOUR "BENT"?

If it is—if you like to tinker with dry cells—if you like to experiment with "wireless"—if you're keen for the columns of "How To Make It" and each new edition of Electrical Experimenter is a fresh revelation to you—then tackle the job in earnest. Study electrical principles. Make a real state. Do it now right on the eve of the big coming era of reconstruction when thousands of men. Now electrical experts will be needed at home and abroad.

Every While You Learn If You Wish—6 day of classes—5 day of paid employment—that is the basis of our "Earn-While-You-Learn" plan.

Hundreds of young men of ambition are taking advantage of the opportunities afforded by electricity to insure for themselves a sound, successful future. Why not decide now to join them? Why not take the first step today? Filling out and mailing this coupon will help you decide. Do it now and get the facts. No obligation whatever.

Spring Term Opens April 1st

**Blue Prints**

Electricians and Garagemen send us 2c for blue prints for buildings and directions for using the tool test and trouble finder. Locates short circuits, opens and grounds in armatures, fields, windings, iron, machining, etc. The Daily Exchange, P. O. Box 209, Dayton, Ohio.

**Stamps**—Unlistated United States or Foreign Stamps, 12c. Philatelic Star, Madison, N. Y.

Stamps—41 different from all countries. Quality Postage Stamp Co., Toledo, Ohio.

We buy and Sell Old Stamps. $2 to $50 each to dealers and collectors. Keep all Old Money. Send 10c for new list. The Exchange, Box 135, Philadelphia, Pa.

**Novelities**

For Sale—Indian relics, all kinds for amateur and professional collectors; specimens get scarce and valuable. If interested, address Harry R. Garber, Quaker City, Ohio.
ELECTRICAL APPLICATIONS

Chemicals—Laboratory Equipment.

Leakproof bottles, chemicals and everything needed, pictures on cloth, Transparent pictures, red and blue pictures, Magic Photos, Plastics, Lamina glass. Chemical Co., Photo Dept., Gettysburg, Pa.

Experiments in Chemistry—Contains chemicals and directions, only two dime each; 24 lot. Mystic Shop, 749 Vito St., E. Waterloo, Iowa.

Chemicals and Laboratory apparatus for analytical and teaching laboratories. F. Krause, 776 N. State St., Chicago, Ill.

WIRE—CABLE—HANGERS—JACKS—CABLE TIES.

Formulas.

25,000 Formulas. $1 postpaid. List 40. Oscar C. Hanson, Mentor, Minn.

Formulas for Every Purpose. H. Krause, 776 N. State St., Chicago, Ill.

Health.

Tobacco or Snuff Habit Cured or not paid: $1.00 if cured. Medley sent on trial. Superba Corp. N.A. 101 St. Mark's Pl., N.Y.

Pyromania—H. E. Kelly, D. S. D., M. D., pyromania specialist for 15 years, has developed a successful method of curing this disease. Full details free. H. E. Kelly, 106 Gladwin Ave., Leonia, N. J.

Motion Pictures.

Motion Pictures selected up. Queen Service, Birmingham, Ala.

Motors, Engines and Dynamos.

Small Motors and Generators: 1/10 to 1/2 horse power, three or four cylinder, plus 500,000 voltages, 1$. C. A., $50 each; 1/2 H. P., $50.00. Battery charger, 1/2 H. P., 1500 wattage, new out of use, $500 each and up. Charging, Lighting and Moving Picture Amplification, Generators, 500.00 each and up. Motors for all phases of current. Immediate delivery. 25c per page. Write for free bulletin. Johnston, West End, Paterson, Penn.

Electric Motors. Let us send you an Electric motor for your Washing Machine, Drill Press, Lathes, Comes Grinders, Air Compressor, Printing Press on a money back guarantee. Are for 160 different uses. We sell them in the cheapest place in country to buy a good motor. S. H. S. Co., 552 Main St., Youngstown, Ohio.

Electric Supplies & Appliances.

Any Formulas $2 for 15c. Recycle your dry batteries. FREE. Z. N. Monter, Warrenton, Mo.

Mr. Businessman—Your advertisement here will be read by over 1000 live prospects. The "pictures" pictures of what they have, bringing the Electrical Experimenter bring quick and positive results. For price and terms, contact Classified Department, 213 Fulton Street, New York.

Instruction

Boys! Learn Electricity my mail! Practical Instruction—25c a lesson. Send 25c for Lesson No. 1. Dr. John W. Western, Engineer, Warrenton, Mo.

Phonographs.

Built Your Own Phonographs and manufacture them for profit. Price List, Blue Prints, etc., complete, sent free. J. H. B. Linhorst, Dept. 6, Cincinnati, Ohio.

Experiencing the world's highest quality spring and electric motors, Tone Arms, Reproducers. Wonderful results. Big saving in apparatus. Catalogue mailed to you for 10c. Small orders only. Indiana Phonograph Supply Co., Indianapolis.

Choralon Phonographs—Special agency proposition selling selling selling, selling Phonographs. Big profits, Write for home agent's special offer and continue the profession. Also supply complete apparatus for setting up phonographs at home. Choralon Phonograph Corp., 2500 Monroe St., Chicago.

Inventions—Patented; Trade-Marks Registered; Labels, Prints and Publications Copyrighted; reasonable fees. Correspondence solicited; detailed information upon written request. John M. McCollum, 208 J. F. McGrew Blvd, Washington, D. C.

John M. McCollum, Atty. at Law. Patents, Trade-Marks, Copyrights, 40 McGrew Blvd, Washington, D. C.

Patents—Fees payable in monthly installments. Paper work kept and attention is given to your needs. Frank Fuller, Washington, D. C.

Patent investigations, save attorney's fees; prepare applications; furnish full instructions and give satisfaction. Free information. Patent Bureau, 295 Seventh St., Washington, N. Y.

Millions spent annually for ideas! Hundreds now wanted! Patent yours and profit! Write today for your free bulletin to protect yourself; how to invent, ideas wanted, how we help you sell, etc. 212 Patent Dept., American Industries, First and Seventh Sts., Washington, D. C.

Fortunes from Patents are made only on inventions that are registered in the United States. Send Sketch or model and $2 for thorough search and honest opinion. I give you free service. Frank Fuller, Washington, D. C.

Inventors! We have a proposition that will probably interest you. Write. Wakefield Engineering Co., 923-C F St., N. W., Washington, D. C.

James D. Gyle, Patents, Trade-Marks and Copyrights. 534 Eighth St., N. W., Washington, D. C.

Inventors for Investors.

Inventors: Before offering your patent for sale, or applying for one, write me. My experience is for 25 years. Established 1895. Charles A. Scott, Department "E", Rochester, New York.

Inventors—Market and secure your inventions through Inventors' World Association, 213 Fulton St., New York. Partnership co-operative organization. Write.

Teletypegrapgy.

Telegraphy, Wire and Wireless, and Railway Acoustics. 25c each. Readable and Understandable demand for both sexes. Big Salaries. Oldest and largest School of Telegraphy in the World. Catalog free. D. S. Dodge Institute, Seventh St., Valparaiso, Ind.

Real Estate Wanted

Sell your property quickly for cash, no matter where located, particularly free. Real Estate Salesman Co., Dept. 98, Lincoln, Nebr.

For sale or royalty Patent 17060, Combination Scot pump and pump for Bicycles and Motorcycles. 25c postpaid.

Letter Specialists.

Song Poems Wanted.

Write the Words for a Song. We write music and guarantee your poems to be sung. Submittal poems on war, love, or any subject. Charles Music Co., 238 Dearborn St., Chicago.

For Men.

Mr. Shaver—for a remarkably keen edge, use "velvashave" barbers compound on your strap. A restriction of 30c per order. Velvashave Barber Agency, Box 60, Oakland, Calif. or Velvashave Agency, Box 60, Oakland, Calif. F. B. Madigan, San Francisco.

Handy Binder

for the ELECTRICAL EXPERIMENTER

Holds and preserves 15 issues, each of which can be inserted or removed at will, without tools. Will keep your magazines wrinkle-free for all time and preserve them like new till you bind them permanently. A made of leather, light, and easily strapped at the back and end. $1.50 per dozen. Price 50c each. Shinny leatherette finish. 60c.

With the consent of NIKOLA TESLA

We have prepared a genuine, handsomely bound, full-sized, hard cover portfolio, containing the greatest man, TESLA, as he is today, holding his famous wireless-lighting globe, advertising whatever on this photo, except for the autograph. Size about 9 x 12". Ready for framing. A striking picture of the greatest inventor for your den, library, laboratory, workshop or radio station. Sent prepaid in strong cardboard tube. Price 50c.

Experiment Publishing Co., 231 Fulton St. Book Department N. Y. City.
Try This Wonderful New

VIOLET-RAY

Machine—10 Days Free!

NOW in your own home you can have wonderful Violet-Ray treatments exactly as are given by eminent physicians and beauty specialists throughout the country. Now you can rid yourself of headaches, cataract, constipation, eczema, insomnia, lumbar, nervousness. Relieve your pain from neuritis, rheumatism, and other disturbances. Multiply your bodily health, vitalize your nerves, double or triple your energy by using Violet-Rays. Sleep better, increase your strength, and improve your appetite and digestion. Soothe your nerves, reduce or increase your flesh. Tone and strengthen the entire system. Beauty your complexion! All with Violet Rays!

Not a Vibrator

The wonderful Violetta is not a Vibrator. It is not a machine that contracts the muscles—it does not shock, it does not pound the muscles—it is absolutely harmless. Violet-Ray administered by the Violetta are wonderful even for infants! Relieve pain and suffering in every part of the body. Simple tests prove that Violet-Rays pass completely through every part of the body, stimulating every cell and organ. It is electricity in its highest remedial form.

Treat Yourself at Home

Here is a partial list of ailments treated successfully, with the Violetta, Violet-Ray Machine.

Asthma
Barber's Itch
Bola
Blackheads
Pulmons
Calsous
Catharsis
Chilblains
Colds
Corns
Constipation
Dandruff
Defebril

Eczema
Eye Disease
Falling Hair
Hay Fever
Headache
Gout
Insomnia
Lumbar
Nervousness
Neuralgia
Neuritis

Obesity
Pains
Paralysis
Piles
Pimples
Pleurisy
Pneumonia
Skin Diseases
Sore Throat
Sprains
Tonsillitis
Whooping Cough

What Physicians and Users Say

Tirzle Prigomen, well known actress, says: "Cheerfully will I add my praise for Violetta. It's the best 'pain chaser' and 'soother' I've had the good fortune to find. It's WONDROUL. It cured my brother of neuritis. At first I was a bit for facial treatments and general massage. I cannot say too much for it." Dr. Bert H. Hog, of Victor, Iowa, says: "I have had good results with the Violetta High Frequency Instrument in all cases of neuritis. Almost instant relief is my experience."

K. L. Allen, Des Moines, Iowa, says: "I have had very good results with the production of Pain Ray Currents in cases of Pneumonia, Eczema and Neuritis, and find it a great help in drugless healing."

Dr. Daniels, Elkom, North Dakota, says: "I have used the VIOLETTA in such cases as Gout, Bronchitis, Pneumonia, Neuralgia, and Insomnia, and find it very beneficial. In fact, I would not be without it in my practice." Frank Borne, Seattle, Wash., says: "I purchased the VIOLETTA for my wife, who was suffering from an acute attack of neuritis. From the very first treatment it brought wonderful relief and we are entirely 'well now.'"

BLEADON-DUN CO., Dept. 2-B, 11-17 So. Desplaines St., Chicago, Ill.

BOOK FREE!

32-page beautifully illustrated free book, describing the Violetta in detail. Read the amazing phenomena produced by Violet-Ray High frequency current. Why it produces stimulation and sedation. How to give spinal treatments with the Violetta, how to treat various ailments, including nervous troubles, rheumatism, obesity, hayfever, skin treatments, facial treatments. Note low price direct to you from our own laboratories. Note the amazing superior construction of the Violetta in every detail. Mail coupon or postal right now before you turn this page. Violet-Rays will double your energy, will increase your life, will remove your pains and aches. Address BLEADON-DUN CO., Dept. 2-B, 11-17 So. Desplaines St., Chicago, Ill.
E VERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering at all levels.

You run into some new electrical problem almost every day. The information you need to help you in your every work day is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a single bound and a reference guide in one, written in plain every language—no wasted words—only what you need to know—check full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of your daily work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

The looks are small enough to slip into your coat pocket—bound hard in durable black cloth. The book is the complete master of its contents. 2,700 pages of actual information and 4,300 illustrations. Once you read these books and put them into actual use you will never again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—all the questions you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes entirely FREE.

This is a sign of our confidence in the guides. Price gold does not object to being talked over them for along without them, return them to us and one us nothing.

When you decide to keep them you only have to pay $1.00 down and return the balance of $1.00 on the day payment of $1.00 a month till paid. Use this coupon to get the books. It will pay you many times over.

THEO. AUDEL & CO.

BE A CERTIFICATED ELECTRICIAN

I WILL TRAIN YOU AT HOME

A REAL POSITION LIKE THIS—FOR YOU

The country needs thousands of trained, Certificated Electricians to fill good positions—and at big pay. It's all a matter of knowing how, and I will teach you by up-to-date, modern instruction. You can learn at home, without interfering with your regular work, by my highly successful method of Home Instruction in Practical Electricity.

Prepare NOW and be ready in a few months to earn your $46 to $100 A WEEK

Send for this Book

My book, "HOW TO BECOME AN EXPERT ELECTRICIAN," has started thousands of young men on the way to splendid success. A new edition of this has just been printed. I want every young man interested in Electricity to have a copy, and will send you one, ABSOLUTELY FREE AND PREPAID. Write me today.

How I Train My Students

As Chief Engineer of the Chicago Engineering Works I know exactly the kind of training a man needs to enable him to get and hold good positions, and to earn big pay. I have trained hundreds of men who are holding splendid electrical jobs.

I give each of my students personal attention and a complete and thorough training. I give him a SPLENDID ELECTRICAL OUTFIT FREE, and much of the training is done by actual work. When my students graduate and receive their Certificate, they are ready for a real position. But still more, at any time you wish you can come to our splendidly equipped Electrical Shops for special training. No other school can give you this.

A Real Opportunity for YOU

Wishing is never going to make your dreams come true. You've got to study—to learn. A man is worth possibly $2 or $3 a day from his neck down—and no more; but there is no limit to what he can be worth from his neck up.

A trained mind is what gets the big pay. It is this training that you need, and I can train you in a few months. Are you ambitious to make a real success—then send me the coupon—today.

Electrical Outfit FREE

To every student who answers this ad I am giving a Splendid Electrical Outfit of standard size Electrical Tools, Instruments, Materials, etc., absolutely free. Furthermore, to every Electrical Student I give a truly valuable surprise that I cannot explain here.

Free Employment Service

I am continually receiving requests from employers to send them trained Electrical men. I assist my students to secure good positions. I keep in touch with them for years, helping and advising them in every possible way.

Write Now—Don't Delay

Delay never gets you anything. Action is what counts. Get started—and get started now. Write me, or send me the coupon, right NOW.

The Burgess BLUE BOOK
for all Practical Men and Electrical Students

(See review of this book by Editor in December issue of your Electrical Experimenter page 568)

I have prepared a pocket-size note book especially for the practical man and those who are taking up the study of electricity. It contains drawings and diagrams of electrical machinery and connections, over two hundred formulas for calculations, and problems worked out showing how the formulas are used. This data is taken from my personal note book, which was made while on different kinds of work, and I am sure it will be found of value to anyone engaged in the electrical business.

The drawings of connections for electrical apparatus include Motor Starters and Starting Boxes, Overload and Underload Release Boxes, Reversable Types, Elevator Controllers, Tank Controllers, Starters for Printing Press Motors, Automatic Controllers, Variable Field Type, Controllers for Mine Locomotives, Street Car Controllers, Connections for Reversing Switches, Motor and Dynamo Rules and Rules for Speed Regulation. Also, Connections for Induction Motors and Starters, Delta and Star Connections and Connections for Auto Transformers, and Transformers for Lighting and Power Purposes. The drawings also show all kinds of lighting circuits, including special controls where Three and Four Way Switches are used.

The work on Calculations consists of Simple Electrical Mathematics, Electrical Units, Electrical Connections, Calculating Unknown Resistance, Calculation of Current in Branches of Parallel Circuits, How to Figure Weight of Wire, Wire Gauge Rules, Ohm's Law, Watt's Law, Information regarding Wire used for Electrical Purposes, Wire Calculations, Wiring Calculations, Illumination Calculations, Shunt Instruments and How to Calculate Resistance of Shunts, Power Calculations, Efficiency Calculations, Measuring Unknown Resistances, Dynamo and Dynamo Troubles, Motors and Motor Troubles, and Calculating Size of Pulleys. Also Alternating Current Calculations in finding Impedance, Reactance, Inductance, Frequency, Alternations, Speed of Alternators and Motors, Number of Poles in Alternators or Motors, Conductance, Susceptance, Admittance, Angle of Lag and Power Factor, and formulas for use with Line Transformers.

WHAT PRACTICAL MEN SAY ABOUT THE "BURGESS BLUE BOOK"

Received your "Blue Book" and must say it is the best book I ever saw. I showed it to a friend of mine and he refused to give it back to me but he paid me a dollar and told me to get another. Rather than be without this book I am sending Money Order for three of them so I can show them to two more of my friends and have one left for myself. Wishing you would send them at once, I am Yours very truly, JOSEPH BRAITH, Electrician.

Your "Blue Book" received and it is just the book I have been looking for. Please mail me three more by return mail for which I am enclosing Money Order. Respectfully,

V. E. JOHNSON, Western Union Tel. Co., Marion, Ohio.

Have received the copy of the "Burgess Blue Book" and am very well pleased with the easily found formulas and data contained in it. I am enclosing Money Order for four additional copies,

THORE C. ANDERSON, Ridgeway, Penn.

I am enclosing three dollars for which please send me three copies of the "Burgess Blue Book". I showed the copy I got last week to some friends and three of them asked me to get them one. Very truly yours,

CHAS. H. DAVIS,
Los Angeles, Cal.

I received your "Blue Book" and after I looked over it I see that it is a very useful book. After I showed it to some fellows they wanted a copy also and I am enclosing Money Order for which please send me three at once. Yours very truly,

R. S. SWANSON,
St. Paul, Minn.

I received the three books I sent for and the next day I sold them. The fellows think they are well worth the price. Please send me three more for which I am enclosing Money Order. Yours very truly,

R. S. SWANSON,
St. Paul, Minn.

AN OPPORTUNITY FOR YOU TO MAKE SOME MONEY

To help get the "Burgess Blue Book" to the men who need it the most, we have established a resale discount to which those who have purchased a book from us are entitled. The "Burgess Blue Book" is not sold through the regular book dealers so we offer the regular book dealers' discount to men who will take orders and send them in to us. In this way the "Blue Book" is only sold by those who know its value and we feel that this arrangement is much more satisfactory to the purchaser, than if he bought it through the regular book-selling channels. The book practically sells on sight, as a man engaged in practical work realizes when he sees it, that it contains information which is extremely useful and which is difficult to obtain in any other way.

The Burgess BLUE BOOK Will Be Shipped, Postpaid, on Receipt of $1.00

Send dollar bill, money order or check. I guarantee satisfaction or will return your money if you decide not to keep the book after using it for five days

BURGESS ENGINEERING CO., YORKE BURGESS, Consulting Engineer
747 East 42nd Street Chicago, Illinois

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
FEW weeks ago Marconi startled the world by stating that he had often received strong wireless signals which seemed to come from beyond the earth. In a recent interview he said: "The fact that extra-planetary signals were recorded in Colorado Laboratory. That was in 1899, before the world dreamed of wireless."

Even today announcements such as the above are made light of by editorial writers and others of limited scientific perception. For the earth-bound layman still persists the intelligence on earth. Such childish reasoning shows what sort of "intelligence" blossoms on this planet. It never occurs to these reviewers to ask question why Nature in her Wisdom should have singled out the little speck called Earth, to which we are endowed with reason. Why should there be such an exception? Life in some form or other is certain of being found on myriads of worlds throughout the universe. And if one world dies, all life does not die with it. Svante Arrhenius shows us how life-bearing spores are carried by the pressure of light thru interstellar space, notwithstanding the absolute zero which prevails there.

In our planetary system, conditions for life, such as we know it, probably only exists on two planets: Mars and Venus. Life on the latter being more or less doubtful, due to its heavy water-laden atmosphere, there remains Mars, a body much older in evolution than the earth. Conditions on Mars we know by direct observation as well as deduction are favorable for life, and we may be certain that it exists there. And if we once grant this, we must also grant that it has existed for hundreds of thousands of years prior to that on earth; consequently Martian civilization must be thousands of years ahead of ours.

From this we must deduce again that the Martians probably signaled to us ages ago, when prehistoric man still roamed the forests. But why go so far back? Suppose the Martians had sent us radio messages only thirty years ago. We could never have received them, for we then had no means of recording them. Detectors and audions were undreamt of. In this all warped logic, we presuppose wireless signals. But why should a civilization so far ahead of ours use—to them—obsolete radio waves, which, like as not, can never hope to bridge 35 million miles? If the Martians are signaling to us, we may be certain that they use an entirely different means from Radio. To be sure, it may turn to be one of the many wave forms of the ether. But we can only make a poor guess at it today. Meanwhile Martian signals probably by about our heads day and night, as they may have for thousands of years, but we are still deaf and blind to them. The Martian Wave Detector still remains uninvited. At that the Martians probably have used many methods on us. It is not even impossible that they may have used reflected sun rays. Bell and Tainter in 1880 demonstrated a "wireless" telephone—the Photophone—by making use of a vibrating light ray falling upon a selenium cell. Speech was transmitted over many miles this way. With necessary refinements such a system might bridge interplanetary space.

As to one planet understanding the other, that is of course child's play. Still, many humorous editorial writers have misgivings. They are said that on Mars \( M + 2 \) might equal, perhaps, 5 or 3, so how could we get together, they ask.

A simple example might serve as an illustration. Suppose an American and a Frenchman, neither knowing the other’s language, were connected by a long telegraph line. Both are ignorant of the code. But both have enough sense to tap the key. Suppose both have the desire to send a message to the other. What will they do? Tap out dots from one to ten, of course. Thus etc. It will not take them many months, if they keep at it, to work out a sort of "international" language by means of dots. And the higher their intelligence, the quicker will they understand each other. That is the basis of interplanetary communication.

H. Gernsback.
We want ambitious men and women to have these remarkable Charts which are a visual demonstration of Chiropractic, the new science of Drugless Healing. This offer is now made to show the opportunities now open to Chiropractors. We also explain how we give a practical training by mail in this dignified, paying profession. If your desire is to enter an uncrowded field—if you want to achieve financial independence and social standing, at least investigate. Your request on the coupon below is all that is necessary.

$3000 to $5000 a Year

Many Doctors of Chiropractic earn $8,000 a year and more; some upwards of $10,000. Dr. M. D. Moore of Ky., reports an income of $9,000 a year. Dr. L. H. Roche, New Jersey, $8,500; Dr. Hanna of Florida, over $8,000 yearly. What others are doing you should be able to do. A diploma gives you the same opportunity—is evidence that you are master of a profession of dignity, prestige and influence.

Our Lessons Teach You

how to make Spinal Adjustments for speedy relief of

Headache  Neurogia
Indigestion  Neuritis
Lumbar  Cataract
Epilepsy  Fever
Pleurisy  Jaundice
Constipation  Dyspepsia
Rheumatism  Paralysis
Asthma  Etc., Etc.

PRACTICAL
As experts Know it
SENT FREE for INSPECTION

Learn electricity as you would in actual PRACTICE—in accordance with the methods employed by the highest paid electrical experts in America. The New McGraw-Hill Library of Practical Electricity contains the actual working facts which you need in order to succeed in the electrical field. Terrell Croft, formerly with the Westinghouse Company, makes the conquest easy for you.

A New Standard in Electrical Literature
The New Library of Practical Electricity by Terrell Croft marks a new era in electrical literature.

The great field of electrical engineering, with its limitless possibilities of earning power, is brought to you in a form that makes success easy. The Library is a creation—an achievement that is without parallel in technical literature, because it sticks to actual practice throughout its 3,000 pages.

A letter that means something to YOU—

McGRAW-HILL BOOK COMPANY, Inc.
239 West 39th Street, New York, N.Y.

Gentlemen: In an attempt to express myself about CROFT'S NEW LIBRARY OF PRACTICAL ELECTRICITY, I have never seen, and do not believe there was ever printed in the English language, a more comprehensive set of books. It is a library that is just as valuable to the novice as to the expert, because it is all practice.

Respectfully,

GUY H. PEIFER,
Chief, Doplan Silk Corporation, Hazelton, Pa.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
ELECTRICITY

Records of actual Work
NOT ONE PENNY IN ADVANCE

You have always wanted a compact set of books containing the solution to all your electrical problems. You have wondered if it were possible for any author to place himself in your shoes, and explain the very problems that face you every day. You have picked up books that covered the other fellow's problems, but not yours. These books seemed to touch on everything except the matters that pertained to your own work.

These books were not complete. They were probably out of date. They were probably not practical.

You have said yourself and heard others say, "I want books that fit into my work. The man who writes those books must understand my work, and know what he is talking about. I want not facts, but theories and the higher spheres of electricity occasionally, but not while I am on the job. Then I want plain facts, plainly stated. I want books that have anticipated my problems and figured them out for me."

Your wants have been anticipated and met in the new Croft Library. It is a seven-year undertaking recently completed by a man whose experience covers the whole field of electrical practice.

Examination will show why Croft's Library is not the massed standard. Why it is used by the highest authority as well as the lowest beginner. Examination will show how it is revolutionizing the methods of teaching the practical side of electricity.

Examination is absolutely free. Merely return the coupon below.

Now is the time to master Electricity—Now is the time to prepare for a high salary

Old books won't do. Amateurish books won't do. Books compiled by "desk authors" or men with no practical experience will not serve your purpose.

Practical books are easiest mastered. Practical books, written by practical men, teach you accurately and rapidly. There is nothing in the Croft Library which you cannot understand. Terrell Croft tells you the secrets of success in electricity in plain words, figures and illustrations. Nothing is left to the imagination. There is no guesswork. There is no theory or higher mathematics.

Send now for these eight volumes. No matter how many books on electricity you possess, you are unfair to yourself unless you take advantage of this free examination privilege. No matter whether you are beginner or expert, these books will show you the clear road to success. Inspection will prove this.

Meet Terrell Croft

Be guided in your study of electricity by an experienced Electrical Engineer of high professional standing. Terrell Croft, author of 7 of these volumes, climbed from the ranks to Electrical Engineer with the Westinghouse Company. He gained his knowledge with his sleeves rolled up and has met your problems in advance. He tells in plain, understandable language how to proceed by the best and most practical methods.

Not one cent in advance—Just the coupon

Examine this new Library for ten full days without expense. Find out for yourself why it is now taking the lead in electrical book sales in America. Use the books as you see fit for ten days. Look at the hundreds of illustrations that clear up all the mysteries in electrical practice. Stick a couple of the volumes in your pockets, and refer to them during the day. Figure out in an instant the problems that have hitherto taken hours. Then send us $2 per month for eight months, or return the set entirely at our expense. You risk nothing by returning the attached coupon.

ELECTRICAL EXPERIMENTER

April, 1919

853

McGraw-Hill Book Company, Inc.,
239 West 39th St., New York.

Gentlemen:
I am enclosing money order for $2.00, which I believe is my last payment on Library of Practical Electricity. I wish to say just a word about the books. I want to go on record with the statement that they are absolutely the best set of books ever published for the man on the job. To have these books and get familiar with them makes one want to meet and talk with Mr. Croft. As a rule books which claim to be self educational are very incomplete and well padded with tables, etc., which one may find at any time in catalogues, but I will say Mr. Croft has certainly gotten away from this. A man who cannot read these books understandably is hopeless. There never was a correspondence course even with the aid of personal letters, that could give a man real knowledge as these books do. I am Chief Electrician at a State Institution here and have used for these books every day. I fear no job because I know that if I cannot solve the problem, I have a friend at home in Mr. Croft's books, who will come to my aid.

Yours truly,
E. E. CONYER
Anna, Ill.

You have always wanted a compact set of books containing the solutions to all your electrical problems. You have wondered if it were possible for any mortal to know as much as you do, and perhaps more. You have come to the conclusion that you must pick up books that cover the entire field of electricity. These books needed to teach so much about the sciences that you feel it is worth while, if you have not finished the work, that you must learn them because you feel that they are absolutely the best set of books ever published for the man on the job. To have these books and get familiar with them makes one want to meet and talk with Mr. Croft. As a rule books which claim to be self-instructional are very unimportant and well paddled with tables, etc., which one may look at any time in catalogues, but will say Mr. Croft has certainly gotten away from all this. A man who cannot read these books understandingly is hopeless. There never was a correspondence course even with the aid of personal letters, that could give a man real knowledge as these books do. I am Chief Engineer at a State Institution here and have used for these books every day. I fear no job because I know that if I cannot solve the problem, I have a friend at home in Mr. Croft's books, who will come to my aid.

Yours truly,

E. E. CONVER
Annex, III

Now is the time to master Electricity—Now is the time to prepare for a high salary

Old books won't do. Anarchic books won't do. Books can't make an expert. A man with no practical experience will not serve your purpose.

Practical books are easy mastered. Practical books, written by practical men, teach you accurately and rapidly. There is nothing in the Croft Library which you cannot understand. Terrell Croft tells you the secrets of success in electricity in plain words, figures, and illustrations. Nothing is left to the imagination. There is no guesswork. There is no theory or higher mathematics. Read now for three clear volumes. Do not buy many books any cheaper. If you are a beginner, read these books to know all about electricity. If you are an expert or engineer, these books will show you the clear road to success. Request will prove this.

Not one cent in advance—Just the coupon.

This is the only coupon ever made by a book company for a book that will save you money. Send this coupon to the McGraw-Hill Book Company, who will send you the book, and you will receive a copy of the first two volumes free. You cannot lose. You'll be surprised to find out for yourself why it is that you can't get a clear notion of electricity from these books. Mr. Croft tells you the secrets of success in electricity without any guesswork or higher mathematics. This coupon is good for every one. Do not delay. Send it now.

239 West 39th Street, New York, N. Y.

FREE EXAMINATION COUPON

Check this offer carefully. You can get a complete examination of the Croft Library by returning this coupon with the coupon above. You are entitled to a complete examination of the Croft Library by returning this coupon with the coupon above.
Master Electricity By Actual Practice

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

The Oldest and Only Institution of the Kind in America

At this “Learn by Doing” School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

Over 5,000 Graduates are Successful Men in the Electrical World

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions.

Let us explain this course to you in person. If you can’t call, send now for 64-page book—it’s FREE to you

New York Electrical School
29 West 17th Street, New York

New York Electrical School

Grand Opera in Your Home

By H. Gernsback

Many thousands of people musically inclined are deprived of hearing our great operatic stars mainly on account of the high price of admission, also because of the limited seating capacity of even our largest opera houses. Take for instance a limited income prefer such seats and, therefore, the gallery is usually made up entirely of really music-loving Italians.

Suppose that all you had to do was to step to the telephone at 8.30 in the evening, no matter if you lived in New York or anywhere else in the country, and immediately connect a loud speaking telephone in order to listen to the transmitted music, it is quite a different problem to connect say twenty or forty thousand subscribers' lines to these microphones and then reproduce the music at the end of all these thousands of circuits. The reason is that heretofore we had no satisfactory instrument whereby the.

New York to Chicago Via the Air in Twelve Hours

A RLINE TICKET for Chicago, Please.” “Yes, sir; five hundred and twenty dollars, Please. The next ‘liner’ leaves in half an hour for Chicago and way stations,” replied the ticket agent of the Trans-Continental Airline Company on a bright Sunday morning in the year 1919. At least that is a fair sample of the conversation we may find quite common in a few months or so, if the plans of one of the largest aeronautical organizations materialize in any such manner as their originators predict. Complete arrangements for the construction and operation of a line of passenger carrying dirigibles between New York and Chicago at an initial charge of sixty-five cents a mile for each passenger have been made by J. M. McElroy, chief engineer of the Sturtevant Aeronautical Company, of Boston, in collaboration with Noble Foss, one of the officials of the corporation and a son of former Governor Foss, of Massachusetts.

Announcement of the big undertaking was made recently by the Massachusetts Aeronautical Corporation, which held its annual aeronautical exposition at Madison Square Garden and the Sixty-ninth Regiment Armory from March 1 to 15, inclusive, in cooperation with the War and Navy Departments.

It is proposed to form a company with four dirigibles and two main terminals, one at New York, the other at Chicago. The dirigibles are to be of the Zeppelin type, with rigid housing and multiple compartment structure. The U. S. War Department’s wonderful new discovery, Helium, will be used, thus removing the danger of fire. The airship will be 425 feet in length and forty-five feet in diameter. Its engines will have a horsepower of 1,200. The bag will have a capacity of 65,000 cubic feet of gas, providing a gross lifting power of twenty tons at sea level. This would mean a practical net lift of ten tons. It is estimated by Mr. McElroy that a speed of seventy miles an hour can be maintained and that the trip from New York to Chicago could be made in comfort in less than twelve hours.

“The cost per mile, roughly speaking,” says Mr. McElroy, “would approach sixty-five cents per passenger, or $520 for the entire trip in either direction. There is no doubt that after the line is run for some time, it will be possible to cut down the rate considerably.”

Each dirigible will have accommodations for twenty-five passengers. The power plant will consist of two engines, side by side, driving thru gears a central stub shaft mounting a variable pitch air screw. With dirigibles is a great problem, Mr. McElroy says: “It is reasonable to believe that hill walled landing zones could be located, or natural depressions in the earth could be enlarged to offer breakaways to permit the air liner to come down safely. The terminals at either end of the New York-Chicago route could be floating piers secured at one end, so as to swing with the wind to permit easy housing of the ship.”

With regard to the possibility of transatlantic flight, Mr. McElroy says: “When we have put the New York-Chicago route into successful operation then it is time to throw a line across the pond and do a real job.”

Apropos of transcontinental aeronautical transportation we find much food for thought in a speech recently made by Allan R. Hawley, president of the Aero Club of America, before the National Rivers and Harbors Congress, at Washington, D. C. on April 19, 1919.
Guiding Airships With the "Radio Barrage"
Invisible Walls of the Ether
By DR. LEE de FOREST

Just at this time, when our army and navy officials, and many airplane builders, are taking steps for the commercial development of the airplane and dirigible, along industrial and governmental lines, is it not practical, as well as advisable for radio inventors and engineers, as well as others concerned, to give thought to those essential safety devices which come within the scope of radio-communication and control?

I venture to say that if there was any one device used in the European war which contributed to the success of the Allies in their supremacy of the air, it was radio-communication, both telephone and telegraph. By means of it the fighters in the air were at all times able to talk and signal with their commanding officers at headquarters, and after a personal examination of the various kinds of apparatus used by the different countries, all of which pay high tribute to American genius, I feel I am fully justified in predicting an even greater use of radio control and communication for peace purposes.

One of the first questions to be taken up, it seems to me, when we have reached the point of regular passenger and freight traffic by air, is that of proper warning to pilots in case of fog, cloud or other interferences. Will it not be necessary, for example, to establish a regular "traffic squad of the air," for those cities in the principal lines of communication? The use of the human voice in sounding a warning, without wires, is already an accomplished fact; at Point Judith Light, where the Radiophone, at regular intervals, calls out to the ship operator: "Point Judith Light," and then in a weaker voice: "You are getting closer—Keep off."

By means of a number of wireless stations placed around any given city, why cannot we do likewise in the matter of our radio traffic squad of the air? So that when a pilot comes within range, he would receive a message such as the following: "Buffalo Office—Turn West by South, and with extraordinarily tall buildings with consequent air pockets.

By arrangement of antenna or reflectors not unlike those used behind large searchlights, a beam, or narrow zone of wireless waves, invisible to the eye of course, could be set up. This would necessitate the use of very short wave lengths, of only a few meters, far shorter than the wave lengths used today in radio-communication. This feature would also have the advantage that these short wave lengths would not interfere at all with existing radio-communication. All this short wave vertical radiation would be controlled by the automatically repeating phonograph, similar to the Radiophone arrangement at Point Judith Light.

The pilot of the airplane, his 'phone
How Electricity Serves World's Largest Hotels

By H. WINFIELD SECOR

The two largest hotels in the world are the Commodore and the Pennsylvania, both located adjacent to the Central Terminal, and built directly on both the Oueensboro and 53rd Avenue subways. There are so many hundreds of innovations and conveniences which have been developed and applied to these—the last word in Hoteldom—that one can hardly judge of the undoubted value of all of these important and elaborate appointments without having actually visited such an establishment.

Hotel Commodore

As one emerges from the railroad tunnels, one is met by the gigantic proportions of the Hotel Pennsylvania with its 2,200 rooms and bath. This hotel has 1,500 guests with rooms, not to mention several dozen additional small-town populations, which it can easily entertain in the grand ball room and its six well appointed restaurants, also numerous private banquet rooms and private dining rooms, not forgetting the roof garden, which is one of the most beautiful and perhaps the largest in the world. Besides a capacity of 3,500 guests with rooms, 3,000 additional guests can be entertained in the several restaurants including the roof garden, or the total capacity of 6,500 guests, which is a respectable little city all by itself. But if you haven't already visited one of these magnificent and beautifully appointed 20th century hotels, you will probably wish to know what conveniences are provided for the guest, and with that in mind, the writer paid a special visit to these establishments and enjoyed an afternoon and evening of entertainment. Both hotels are housed in the seating of the flowering palms and the aroma of one dollar Hayana perfects among the rooms, which are all designed with the same care and grace as the main lobby. This wonderful lobby is furnished in handsome imported marble and is lighted by reflected light from the main lobby. This richly designed leaded glass ceiling. Both the Hotel Pennsylvania as well as the Hotel Commodore have the same transit facilities, in each case leading from the railroad terminals directly into the hotels, and special elevators for this service to carry the guests to the floor of the main lobby or vestibule. If one arrives by subway or up downtown New York, he finds the same conveniences awaiting him, and is whisked from the street to the floor of the main lobby by elevator, which is operated by young women attired in spic and span uniforms. There is even a woman water starter—and speaking of elevators, the Hotel Pennsylvania boasts of a total of 27. In the following description of the elevators, which will be given presently to them, the Hotel Pennsylvania is inferred, except where otherwise mentioned.

On arriving on the floor of the main lobby, which is 70 feet wide and 360 feet long, one finds that the principal and most important conveniences of the Hotel Commodore other than the accommodations immediately accessible and available from the lobby are the main Din-}

ing Room, the Palm Room, used for after-noon teas, the swimming pool, the bar, the grill room, and in the basement the most attractive barber shop imaginable, reclining leather lounges, and adjacent to these the handsomest array of lady manucurists ever seen this side of Paris. While dining in the grill room, you may if you wish have a one-step or two with your guest on the highly polished dancing floor in the center of the room, while the Original Dixy Jazz Band, with its cornet, trumpet, clarinet, and other instruments, will make you feel that you have in this room a perfect Jazz Band. The Hotel Pennsylvania, accordingly, has a "Quick Lunch Restaurant," which will accommodate several hundred guests, who may wish to enjoy a 15c or 25c meal. That is what you call real service, and both of these hotels are out for service with a capital "S." First, last and always. Later, when you are assigned to the guests' floors and see the layout of the rooms, you will find that these hotels undoubtedly count on a heavy, irregular trade, and in most cases of considerable duration, consisting of from one to three rooms and a bath.

The lower part of the hotel is well shown in the accompanying illustration, and of course there are many rooms and conveniences not shown for obvious reasons, owing to the angle of the mezzanine floors, etc., which cannot be brought out in the limited size of our prints. Just above the main or street floors, contain the private offices, and also there are sleeping and living quarters on these floors for the employees. On the third floor and above is the "Grand Ball Room," which is most beautifully decorated in pleasing colors which do not jar to the eye as do some of these large public rooms in similar establishments. The general decorative scheme throughout the hotel, it may be said, is one of good taste and fitness. The service is carefully worked over to give this feeling at every turn.

The largest private telephone exchange extant, with capacity for 3,340 extensions, 260 trunk lines and 23 operators is connected to the various rooms and other parts of the building. There is located on this floor a telephone exchange. In the telephone exchange are located a large battery of "Telautographs"—the electric telegraph. And both of these recently opened hotels have been very lavish in their telautograph equipment. The Hotel Pennsylvania uses over 200 telautographs, and more will undoubtedly be added later as demands require them. The telautograph equipment at this hotel is built and operated by skilled engineers, and it undoubtedly is one of the best that the writer has ever seen. Its operation will be described in detail with reference to the telautograph system anon, and for the present it will be of interest to the reader to note what happens when a guest is to be paged. In most hotels, at least in the smaller hotels, a guest is not paged except in the main lobby and dining room, but at the "Pennsylvania," when an outsider wishes a party on the telephone, the operator writes down the name of the person who is wanting the call, and then takes it to the telephone operator,—(and they are all good looking, take it from your Uncle Dudley, for he had the good luck to actually visit this "holy of holies," the floor of which no man may enter, excepting that he has a pass signed by the powers that be in the telephone world).—proceeds to write the name on the transcribing paper of his telautograph, there being a telautograph for each of the 23 telephone operators, and simultaneously the written name appears on the main dining room, grill, bar, roof garden and the office, as well as at the bell captain's office in the main lobby, so that when the name is called out by one of the bellhops in your vicinity, you can rest assured that the same name is being called simultaneously in about ten other parts of the building, and for other purposes; it promotes speed in locating the guest, which is sometimes a very important factor, and also lends to the multiplicity of the system, it renders tervised certain of the locating of the desired party, which would not be the case under ordinary conditions. To mention the steam used for heating, is truly enormous in a building of this size, which covers a whole city block, and while talking to the chief engineer of the building, it was ascertained that the total light and power load for the hotel would require as much as 1400 K.W., or about 1900 horse power. Electricity is used in a general way for many purposes and important operations conducive to the efficient operation of the hotel, which the average guest never sees or even dreams of. For instance, how do you suppose the ventilation of such a large hotel as this is taken care of? The chief engineer answers this question by taking you down to the sub-basement two stories underground, where you see one of the largest electric motor units in the world, covering a quarter of a square city block. Here dozen of powerful electric motors rated at anywhere from 50 horse-power each, drive gigantic blowers or fans, each of which is connected up with certain air ducts leading to various parts of the building. Here is the air that is pumped which promotes the proper circulation thru the hallways, and the rooms of the building. Neither of these monster hotels has a gas fire of its (Continued on page 915)
FULL STORY OF THIS LATEST NEW YORK HOTEL—A VERITABLE CITY IN ITSELF—ON OPPOSITE PAGE.
Seeing Thru You Without X-Rays
The New Shadow Photography
By BATTELL LOOMIS

WHAT of the infra-red ray in photography? Is its penetrative power the equivalent of the ultra-violet, or actuating principle of the X-ray? Has Dr. Paul S. Hunter, former State Secretary of Health for Colorado, and bailing from the city of Denver, stumbled on something he didn't know and doesn't know yet, in looking for something he happened? That is a question it may take time and development to answer, but which the writer is content only to raise by way of introduction to a story which has its element of humor because it relates a serious discovery, worth thousands of dollars to society at large, the discovery will not relieve its discoverer one penny. In which it is not unlike many other important scientific discoveries.

One night Dr. Hunter was waiting for a car. He held a flashlight in his hand, and covering the ray, was attracted by the marked red glow of his flesh. He noted the dim shadows of the bones in his fingers, "Jim," said he, "the red rays come thru. If the rays were more vivid, the shadow of the bones would be sharper. I can intensify them and I'll bet I can photograph that."

The idea took hold. The doctor was a user of the X-ray, but he found it easier in ordinary practise to bring in the whole X-ray than to take the weighty apparatus with its coils and cots to the patient. When a man in the country doctor it would be if he could make a fracture diagnosis with an ordinary camera! The X-ray is of value only to the rich and the very poor who receive free treatment. The middle class must pay more than it can afford or won't.

So Dr. Hunter seized the first opportunity to lay his hand on a naked panchromatic photo plate and expose it to the electric light for a moment. It was not very sharp, but it was beginning. He reasoned it out: "It wants only a concentrated light from a point to cast a clearer shadow. This ray must go thru a camera which protects the plate from random rays and I have a good bone picture," he argued.

Accordingly he employed his mechanical knack to construct a black box with an opening at one end large enough to receive his hand or foot. See illustration of the apparatus used by Dr. Hunter, herewith. He made it collapsible so it would fit in a physician's grip. He fitted an iris diaphragm in the top of his box. Then to a plate-holder on the bottom with a developing box beneath that, into which the plate goes with the instant of its exposure, for speedy developing. He then secured a Watten F or extreme red ray filter and placed it above his lensless shutter and diaphragm. He placed his hand over the holder, and squeezed his bulb for a half second exposure. The result was the excellent bone picture shown herewith, with the picture taken entirely with a filtered light—the light that passes most easily of all visible light, thru blood. The discoverer has made with one of the most promising his camera, which is not essential to success. He has merely combined a stock Eastman panchromatic photo plate brushed with a coat of solution to intensify its sensitiveness, with an F-ray filter and a fine point of light to do simply what Röntgen earned his fame for doing in a round about and costly way. He has made a discovery which he proffesses every schoolboy will at once begin to play with, and every doctor to tax in business.

And he has given his discovery freely to the world. He does not intend to secure patents either on his combination of materials or on his panchromatic plates, which may be made in any size and open at both ends to fit different portions of the limbs. Whether the rays will penetrate the trunk for abdominal and intercostal examinations he does not know from practice, which he contends they might be made to do so by improved technique, such as making a long intense ray of light and a more sensitive plate.

Further Dr. Hunter has said, "My claim is that with a box fitted out in this manner and a box of panchromatic plates a physician can tell whether a broken arm is set right before leaving the house, and that it will undoubtedly be used all over the country for that purpose."

"The machine can be improved by using a roll of film if the manufacturer will go over it, and so away with glass plates; the developing tank at the bottom would be adapted to films. The whole outfit is, moreover, made to fold up flat and occupy very little space."

"These pictures could also be made with a camera using a powerful arc lamp to throw the rays thru the human body, and if plates could be made sensitive enough, pictures of the heart's action could be made on celluloid rolls, giving moving pictures of the heart action and other organs of the body. So far I have only used it for extremity work and it has proved very valuable.

"I give the idea to the world with the hope that someone will further develop it, and by improved design and more sensitive plates be able to make pictures as well as with this $2.00 outfit as with a $1,000 X-ray machine."
The front cover picture, showing the bone structure of a woman, gives us a clear idea of how the full figure would appear, using, of course, a sufficiently strong light source, such as an arc lamp. A triskel or template would be cut out to just fit the outer contour of the body, thus giving the maximum X-raying power available in any case. The flimsy portions of the body would appear red just as our artist has shown them, in contradistinction to the usual X-ray image observed in a fluoroscope, where the outline of the flesh is just discernible. It would seem that this new direct light system of bone photography would be much less harmful to the patient, as the X-ray's own detrimental effect when applied in reasonably large dosages, and in some cases cause growths and burns which are incurable.

WAR ACHIEVEMENTS OF U.S. SIGNAL CORPS

When the American forces came to France "communication" was one of the first efforts to which American ingenuity and invention was directed and the Signal Corps, under which communications fall, met it as have the organizations of the American Expeditionary Force. Existing French telegraph and telephone systems were overburdened. There was left for Uncle Sam and Brig. Gen. E. Russell, chief signal officer, and his staff of experts tackled the job.

What they have done in construction is shown in the following statistics: The Signal Corps has built approximately 1,750 miles of poles on which it has strung about 4,775 miles of wire. In addition it has strung about 2,000 miles of American wire as well as existing systems. The Signal Corps has maintained its own personnel and in addition some 3,000 miles of leased wires are maintained by it. All this construction has been made by Signal Corps battalions with implements and material from the United States, with the single exception of poles, most of which were obtained in France.

THE JOHN FRITZ MEDAL FOR GENERAL GOTHALS

The John Fritz Medal of Award, composed of representatives of the National Societies of Civil, Mining, Mechanical and Electrical Engineers, held their annual meeting for 1919 at the Engineers' Club, January 17, and awarded their gold medal to George W. Goethals, the builder of the Panama Canal.

The medal has previously been awarded to Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas A. Edison, Charles T. Porter, Alfred Noble, Sir William Henry White, Robert W. Hunt, John Edison Sweet, James Douglass, Elihu Thomson, Henry M. Howe and J. Waldo Smith.

Col. John J. Carty, now in France, has been Chairman of the Board, but in his absence Ambrose Swasey, of Cleveland, presided.

George H. Post has been elected Chairman for 1919 and W. F. M. Goss, Treasurer, in place of F. R. Hutton, who died during the year.

NEW MARCONI INVENTION EXPLAINED

A joint meeting of the Institute of Radio Engineers and the New York Electrical Society was held on Wednesday evening, March 5, at the Engineering Societies Building, at which Prof. A. Weagant, chief engineer of the Marconi Wireless Telegraph Company of America, read a paper on "Reception through Strays and Interference." The recent announcement of Mr. Weagant's discoveries and inventions in connection with wireless telegraphy created wide sensation.

THE AERIAL PASSENGER LEFT BEHIND

We all know of the taxicab clattering down the street at breakneck speed with the belted passenger making a bee-line for the dock and just arriving in time to see the gang plank pulled in and missing the Liverpool steamer. But the American business man, nothing daunted, by such a trivial occurrence promptly charters a fast harbor boat, races the steamer down the bay, overtakes it and is hoisted up to the deck in time for lunch.

A few years from now humanity probably will not have changed much, and we will still have with us the late passenger. Only this time he will not race down to the dock but up a 40- or 40-story elevator trying to catch the Trans-Atlantic Flier, but just in time to see the big bird "take the air."

Will the American business man of 1925 bawl his lot and return dejectedly to his home? Not if he can help it! He will signal a passing taxiplane which will come down on this huge platform which a few minutes ago harbored the great Trans-Atlantic Flier.

Twenty minutes later, the fast little air-flier will have overtaken the big air monster and after depositing the belted passenger on the upper deck of the European bound flier—not to forget the violent language of our businessman who thinks he has been overcharged by the modern bandit of the air—he will go to his deck chair and begin perusing the latest edition of the Electrical Experimenter.

While the taxiplane might land directly on the big European-bound flier, such a method might be more or less fraught with danger. Mr. H. Gernsback suggests that the transfer of the passenger might be accomplished much easier, as shown in our illustration. The taxiplane would fly about 200 feet above the deck of the big flier, in the same direction and at the same speed as that of the large machine. The passenger could then descend from a rope ladder and drop to the deck with ease, as well as without danger.

YOU CAN WHIT-TLE THIS IRON

It is well known that rapid cooling of hot metals hardens them. That the opposite is true has recently been demonstrated in striking proof by the General Electric Co. One of their scientists annealed American iron surrounded by hydrogen gas for three hours at a temperature above 1,600° F. The product was very little harder than the same iron before annealing, and could be whittled with a jack knife.

One of the largest electric plants in the world is planned to supply power for nearly all the mines at Johannesburg, South Africa.
Locating Stolen Diamonds by X-Rays

Possibly you will remember having read from time to time of the remarkable tricks resorted to by the native diamond miners in the great Kimberly diamond region in South Africa and other parts of the world. So great has the temptation often become to steal diamonds, especially when an extra large one may have been suddenly unearthed, that these natives have been known to resort to the most unbelievable tactics in order to carry the diamonds out of the mine and to withstand inspection even when stript, as practically all of them are, before they leave the mine at the end of the day’s labor.

One of the successful schemes which has been worked out by the superintendent of a large South African diamond mine is shown in the accompanying illustration, and it involves the use of a powerful X-ray machine having several X-ray bulbs excited simultaneously. As each miner passes before the X-ray bulbs, the examiner looks thru his fluoroscope and rapidly swings it up and down, so as to take in the entire examination quickly indicates the presence of the diamond.

Of course, the logical question that arises is—How can the X-ray detect the presence of a diamond inside of the body, especially when it may be temporarily lodged by the clever thief in proximity to large or fairly large bone structures, which would seem to preclude any possibility of detecting the precious stone? However, a perusal of a table showing the various transparencies of different materials under the X-ray will give the solution to the problem. It has been found that the diamond has a different transparency than any ordinary materials, including the bone and flesh of the body, which might happen to be in proximity to it at the time of such an X-ray examination. Also the diamond is a most peculiar substance, and it has certain fluorescent properties which render the facility of its detection all the more possible under an examination by X-ray, as it has a tendency to fluoresce or glow slightly when under the influence of X-rays; which phenomenon is readily detected on a sensitive fluorescence or X-ray screen.

The X-ray machine here shown is connected to a强大的 powerful X-ray tubes of the latest Coolidge type, as otherwise if the tube had to be moved up and down behind the subject, considerable time would be lost in performing this operation and when several hundred subjects have to be examined in a very short space of time, it can readily be imagined that such a device as here shown is imperative.

GIANT SUBMARINES HAVE 12-INCH GUNS AND STEAM PULSION.

We are now able to publish a photograph of one of the most jealously guarded secrets of the British Navy. While the Germans have been constructing submarines capable of matching the largest destroyers almost and of fighting even cruisers and battleships on a surface contact.

The secret of these boats was their great size and speed and the fact that while on the surface they used steam as their propelling power, carrying two funnels like an ordinary surface warship. One photo shows a British "K" class, two funnel submarine "steaming" on the surface at sea. This is the largest class submarine produced by any nation and is 340 feet in length. It outclasses any U-boat built by Germany. Great Britain has a whole fleet of these sea terrors. Storage batteries and motors are used while running submerged.

The other photo shows a new British monitor submarine with a 12-inch gun, capable of giving battle to most any class of armed ship under favorable conditions. So far as known this is the first photograph to be received in this country showing Great Britain's combination of the U-boat and coast defense vessel. The 12-inch gun is the largest that was ever mounted on a submarine.

The Latest British Style in Submarines. It Is Capable of a Speed of 34 Knots on the Surface. When Propelled by Its Steam Power Plant, the Two Smoke Stacks Fold Down When the Submarine Submerges, and It Is Then Propelled by Storage Batteries Previously Charged. While Running Afloat, This Giant Craft Is 340 Feet in Length, and Is Armed with Three 4-Inch Guns, Two Forward and One Aft, as the Photo Shows. The Displacement of This Boat When Submerged Is 2,700 Tons and the Speed 10 Knots.
STEREOSCOPIC MOVIES

The accompanying illustration shows a possible later-day development of the present moving picture, which, although it has been greatly perfected in the past few years, leaves considerable detail yet to be worked out. No matter how clear or flickerless a motion picture may be when viewed on the screen as projected by modern moving picture machines, it would still be one hundred per cent more perfect to our vision, if it could be thrown on the screen in duplicate or stereoscopic fashion in a similar manner to the parlor stereoscopes which we have all seen and used. Of course, if we ever do get to the stage of stereoscopic movies, the screen could be properly viewed and focussed. These would of course be fitted with proper lenses for the purpose.

It might seem off-hand that this latter refinement would be unnecessary, but it is really one of the great marvels of science that causes us to see the images stand out, as it were, from the picture, when we look thru a stereoscope at the photographs or other views mounted in duplicate. The stereoscope operates on a very simple and yet peculiar physiological arrangement, based on the inter-section of the optical powers of the two eyes when they are focussed on two properly made and similar images.

Of All the "Movie" Inventions That Have Passed Our Way, We Have Yet to See Exploited, at Least Commercially, the "Stereoscopic Movie." If You Have Ever Used a Parlor Stereoscope Then You Will Appreciate What a Wonderful Improvement This Idea Would Make in the "Movie" Show, for Then the Figures Would Actually Stand Out in Relief. A Special "Stereoscope" Would Be Placed on Every Seat. Try This Experiment—Hold a Small White Card Vertically Between the Two Similar Views Here Shown, Move the Page Up and Down Until the Images Appear in Relief.
My Inventions
By Nikola Tesla

III. MY LATER ENDEAVORS
The Discovery of the Rotating Magnetic Field

At the age of ten I entered the Real Gymnasium which was a new and fairly well equipped institution. In the department of physics were various models of classical scientific apparatus, electrical and mechanical. The demonstrations and experiments performed from time to time by the instructors fascinated me and were undoubtedly a powerful incentive to invention. I was also passionately fond of mathematical studies and often won the professor's praise for rapid calculation. This was due to my acquired facility of visualizing the figures and performing the operations, not in the usual intuitive manner, but as in actual life. Up to a certain degree of complexity it was absolutely the same to me whether I wrote the symbols on the board or conjured them before my mental vision. But free-hand drawing, to which many hours of the course were devoted, was an annoyance I could not endure. This was rather remarkable as most of the members of the family excelled in it. Perhaps my aversion was simply due to the predilection I found in undisturbed thought. Had it not been for a few exceptionally stupid boys, who could not do anything at all, my record would have been the worst. It was a serious handicap as under the then existing educational regime, drawing being obligatory, this deficiency threatened to spoil my whole career and my father had considerable trouble in railroad me from one class to another.

In the second year at that institution I became obsest with the idea of producing continuous motion thru steady air pressure. The pump incident, of which I have told, had set afire my youthful imagination and impressed me with the boundless possibilities of a vacuum. I grew frantic in my desire to harness this inexhaustible energy but for a long time I was groping in the dark. Finally, however, my endeavors crystallized in an invention which was to enable me to achieve what no other mortal ever attempted. Imagine a cylinder freely rotatable on two bearings and partly surrounded by a rectangular trough which fits it perfectly. The open side of the trough is closed by a partition so that the cylindrical segment within the enclosure divides the latter into two compartments entirely separated from each other by air-tight sliding joints. One of these compartments being sealed and once for all exhausted, the other remaining open, a perpetual rotation of the cylinder would result; at least, I thought so. A wooden model was constructed and fitted with infinite care and when I applied the pump on one side and actually observed that there was a tendency to turning, I was delirious with joy. Mechanical flight was the one thing I wanted to accomplish alotho still under the discouraging recollection of a bad fall I sustained by jumping with an umbrella from the top of a building. Every day I used to transport myself thru the air to distant regions but could not understand just how I managed to do it. Now I had something concrete—a flying machine with nothing more than a rotating shaft, flapping wings, and—a vacuum of unlimited power! From that time on I made my daily aerial excursions in a vehicle of comfort and luxury as might have befitted King Solomon. It took years before I understood that the atmospheric pressure acted at right angles to the surface of the cylinder and that the slight rotary effort I observed was due to a leak. Tho this knowledge came gradually it gave me a painful shock.

I had hardly completed my course at the Real Gymnasium when I was prostrated with a dangerous illness or rather, a score of them, and my condition became so desperate that I was given up by physicians. During this period I was permitted to read constantly, obtaining books from the Public Library which had been neglected and entrusted to me for classification of the works and preparation of the catalogues. One day I was handed a few volumes of new literature unlike anything I had ever read before and so captivating as to make me utterly forget my hopeless state. They were the earlier works of Mark Twain and to them might have been due the miraculous recovery which followed. Twenty-five years later, when I met Mr. Clements and we formed a friendship between us, I told

Mr. Tesla's articles started in our February issue
him of the experience and was amazed to see that great man of laughter burst into tears.

My studies were continued at the higher Real Gymnasium in Carlstadt, Croatia, where one of my aunts resided. She was a distinguished lady, the wife of a Colonel who was an old war-horse having participated in many battles. I never can forget the three years I past at their home. No fortress in time of war was under a more rigid discipline. I was fed like a canary bird. All the meals were of the highest quality and deliciously prepared but short in quantity by a thousand percent. The slices of ham cut by my aunt were like tissue paper. When the Colonel would put something substantial on my plate she would snatch it away and say excitedly to him: "Be careful, Niko is very delicate." I had a voracious appetite and suffered like Tantalus. But I lived in an atmosphere of refinement and artistic taste quite unusual for those times and conditions. The land was low and marshy and malaria fever never left me while there despite of the enormous amounts of quinin I consumed. Occasionally the river would rise and drive an army of rats into the buildings, devouring everything even to the bundles of the fierce paprika. These pests were to me a welcome diversion. I thinned their ranks by all sorts of means, which won me the unenviable distinction of rat-catcher in the community. At last, however, my course was completed, the misery ended, and I obtained the certificate of maturity which brought me to the cross-roads.

During all those years my parents never wavered in their resolve to make me embrace the clergy, the mere thought of which filled me with dread. I had become intensely interested in electricity under the stimulating influence of my Professor of Physics, who was an ingenious man and often demonstrated the principles by apparatus of his own invention. Among these I recall a device in the shape of a freely rotatable bulb, with tinfoil coatings, which was made to spin rapidly when connected to a stationary machine. It is impossible for me to convey an adequate idea of the intensity of feeling I experienced in witnessing his exhibitions of these mysterious phenomena. Every impression produced a thousand echoes in my mind. I wanted to know more of this wonderful force; I longed for experiment and investigation and resigned myself to the inevitable with aching heart.

Just as I was making ready for the long journey home I received word that my father wished me to go on a shooting expedition. It was a strange request as he had been always sternly opposed to this kind of sport. But a few days later I learned that the cholera was racing in that district and, taking advantage of an opportunity, I returned to Gospic in disregard of my parents' wishes. It is incredible how absolutely ignorant people were as to the causes of this scourge which visited the country in intervals of from fifteen to twenty years. They thought that the deadly agents were transmitted thru the air and filled it with pungent odors and smoke. In the meantime they drank the infected water and died in heaps. I contracted the awful disease on the very day of my arrival and alto surviving the crisis, I was confined to bed for nine months with scarcely any ability to move. My energy was completely exhausted and after the second time I found myself at death's door. In one of the sinking spells which was thought to be the last, my father rushed into the room. I still see his pallid face as he tried to cheer me in tones belying his assurance. "Perhaps," I said, "I may get well if you will let me study engineering." "You will go to the best technical institution in the world," he solemnly replied, and I knew that he meant it. A heavy weight was lifted from my mind but the relief would have come too late had it not been for a marvelous cure brought about thru a bitter decoction of a peculiar bean. I came to life like another Lazarus to the utter amazement of everybody. My father insisted that I spend a year in healthful physical outdoor exercises to which I reluctantly consented. For most of this term I roamed in the mountains, loaded with a hunter's outfit and a bundle of books, and this contact with nature made me stronger in body as well as in mind. I thought and planned, and conceived many ideas almost as a rule delusive. The vision was clear enough but the knowledge of principles was very limited. In one of my inventions I proposed to convey letters and packages across the seas, thru a submarine tube, in spherical containers of sufficient strength to resist the hydraulic pressure. The pumping plant, intended to force the water thru the tube, was accurately figured and designed and all other particulars carefully worked out. Only one trivial detail, of no consequence, was lightly dismissed. I assumed an arbitrary velocity of the water and, what is more, took pleasure in making it high, thus arriving at a stupendous performance supported by faultless calculations. Subsequent reflections, however, on the resistance of pipes to fluid flow determined me to make this invention public property.

Another one of my projects was to construct a ring around the equator which would, of course, float freely and could be arrested in its spinning motion by reactionary forces, thus enabling

(Continued on page 105)
The Moon's Rotation

By NIKOLA TESLA

SINCE the appearance of my article entitled the "Scientific Euphorias on the Earth's Surface" in my February issue, I have received many letters of friends criticizing the views I express regarding the moon's "axial rotation." These have been partly answered by my statement to the New York Tribune of February 23, which allow me to quote: In your issue of February 2, Mr. Charles E. Manierre, commenting upon my article in the Electrical Experimenter for February, which appeared in the Tribune of January 21, says: "I am sure it is a definition of axial rotation."

I intended to be explicit on this point as may be judged from the following quotation: "The unfailing test of the spinning of a mass is, however, the existence of energy of motion. The moon is not posses of such vis viva." By this I meant that "axial rotation" is not simply "rotation upon a line not collineally defined in diameter," but is a circular motion in the true physical sense—that is, one in which half the product of the mass with the square of its velocity is a definite and positive quantity. The moon is a nearly spherical body, of a radius of about 2,160 miles, from which I calculate its volume to be approximately 3,500,260,360 cubic miles. Since the mean density of one cubic foot of material comprising it weighs close on 205 lbs. According, the total weight of the satellite is about 27,900,000,000,000,000,000,000, and its mass 2,482,500,000,000,000,000 terrestrial tons. Assuming that the moon does physically rotate upon its axis, it forms one revolution in 27 days, 7 hours, 43 minutes and 11 seconds, or 2,360,591 seconds. If, in conformity with mathematical principles, we imagine the entire mass concentrated at a distance from the center equal to two-fifths of the radius, then the calculated rotational velocity is 3.04 feet per second, at which speed the globe would contain 11,474,000,000,000,000,000,000 short tons of energy sufficient to run 1,000,000 horsepower for a period of 1,323 years. Now, I say, that there is not that energy in the moon to the most delicate watch.

In astronomical treatises usually the argument is advanced that "if the lunar globe did not turn upon its axis it would exhibit the same terrestrial view. As only a little over one half is visible it must rotate." But this inference is erroneous, for it only admits of one alternative, that there are an infinite number of axes besides its own in each of which the moon might turn and still exhibit the same peculiarities. I have stated in my article that the moon rotates about an axis passing thru the center of the earth, which is not strictly true, but it does not vitiate the and direction to the motion preceding. By way of illustration—if the ball is whirled on the string clockwise ten times per second, then when it flies off, it will rotate on its axis ten times per second, likewise in the direction of a clock. Quite different are the conditions when the ball is thrown from a sailing. In this case a much more rapid rotation is imparted to it in the opposite sense. There is no true analogy to this in the motion of the moon. If the gravitational string, as it were, would snap, the satellite would go off in a tangent with a velocity of swerving or rotation, for there is no moment about the axis and, consequently, no tendency whatever to spinning motion.

Mr. Manierre is mistaken in his surmise as to what would happen if the earth were suddenly eliminated. Let us suppose this to occur, at the instant when the moon is in opposition. Then it would continue on its elliptic orbit of the sun, presenting to it steadily the face which was always exposed to the earth. If, on the other hand, the latter were to be removed, the moment of conjunction, the moon would gradually swing around thru 180° and, after a number of oscillations, revolve again with the same face to the sun. In either case there would be no periodic changes in the solar day, and night would respectively, on the sides turned towards, and away from, the luminary.

Some of the arguments advanced by the correspondents are ingenious and not a few comical. None, however, are valid.

One of the writers imagines the earth in the center of a circular orbit plate, having fixedly attached to its peripheral portion a disk-shaped moon, in fractional or geared engagement with another disk of the same diameter and freely rotatable on a pivot projecting from an arm entirely independent of the planetary system. The arm of this mechanism is then simultaneously in its pivot disk of course, is made to turn on its axis as the orbital plate is rotated. This is a well-known drive, and the rotation of the pivoted disk is as palpable a fact as that of the orbital plate. But, the moon in this case only revolves about the center of the system without the slightest angular displacement on its own axis. The same is true of a cart-wheel to which this writer refers. So long as it advances on the earth's surface it turns on the axis in the true physical sense; when one of its spokes is always kept in a perpendicular position the wheel still revolves about the earth's center, but model rotation has ceased. Those who think that it then still exhibits all laboring under an illusion.

An obvious fallacy is involved in the following abstract reasoning. The orbital plate is assumed to gradually shrink, so that finally the earth is reduced to a point and the distance between the two planets to the radius of the moon without affecting the system in principle, but a further diminution of the distance is main (Cont. on p. 892)
PHYSICS AND THE WORLD WAR.

A fitting conclusion to this series of articles, let us consider to what extent Physics helped to beat the Huns. The bulk of the wonderful work done by all branches of science has as yet not been

Wireless Telegraphy — It Often Proved the Only Reliable Communication in Battle.

University of Chicago, in his address at the Philadelphia meeting of the American Institute of Electrical Engineers, and by Major-General Squier in his address at the New York meeting of the A. I. E. E, is more than sufficient to make it evident to us that Science in general and Physics in particular, deserves a lion’s share of the glory accruing from the victory of the Allies.

The American public at the beginning of the war held its scientific men in insignificant regard, and was very much surprised to learn of the high degree of mobilization of Germany’s scientific men for war work. The “fool professor” was desired to come before the public eye. On our entry into the war our wizard inventors with their efficient agents won the war for us over night by their epoch-making inventions. Days went by, and our epoch-making inventions did not appear, and generally the usual murder and divorce cases appeared in the papers again, displacing the names and ideas of our wondrous newspaper wizards. An Inventions Board received some 1,600 inventions from our inventors and found about half a dozen of them were worth considering. Magnets of tremendous size were proposed, which when placed in the bottom of the sea would attract all shells, etc., and thus stop the war.

Others proposed magnets of various forms, which on trailing their cable behind an airplane would drag up any submerged invaders in the sea. Another proposed generating a wind so strong that it would push away any approaching airplane, balloon, etc. Thus airplane raids were eliminated, submarine attacks were ended, and the war was over. These fool inventions were coming in so fast that the Board in self-defence determined not to consider any inventions sent in by these wonder-workers unless a “working model” accompanied the paper. It was evident that the road to a successful termination of the war lay in bringing together men possessing scientific knowledge, and equipped with scientific methods. In ordinary peace times the college professor is at a disadvantage — he is usually ignorant of, or not interested in commercial development, and does not come in contact with the technical trades. However, his researches in pure science are eventually commercialized and become of vast technical importance. In bringing together such men and presenting them with problems, showing them the conditions, having them perform their researches and publish results immediately, making use of the fruit of their toil — this proved the way to victory. In Washington, London, Paris and Rome, some of the foremost of the Allied scientists were gathered. Among the Physicists we have Millikan, Amos, Mendehall, Gale, Wood, Huff, Hubbard and others, all in uniform and commissioned as officers in the U. S. Army or Navy. Major-General G. O. Squier, the Chief Signal Officer of our army, is a Physician of considerable reputation, having received his degree of Ph.D. in Physics at Johns Hopkins University. The rest of our Physicists served in civilian capacities.

Let us now see how our war needs affected scientific research. It is a well-known property of charcoal that it has a high absorbing power for many gases. The Physicist was brought forth their little surprise of “poisonous gas” the gas mask was immediately evolved. Research developed a special treatment of the charcoal, made in certain sizes from special charcoals, which wood had an increased absorbing power. The Physicist knew that charcoal had this absorbing power, and when the problem of making an absorbing power for the combatting of gas warfare more efficient was proposed, the problem was solved. Airplane engines have been in use for many years, but never before has the necessity arisen for high speed quantity production. The problem arose and was solved, the airplane engine was designed, developing 400 horse-power and weighing only 800 pounds; about 2,000 per month were manufactured. The resistance offered by the wings of different sections, the stability of the airplane, the characteristics of the covering surfaces, etc., have all been investigated in detail. The instruments of navigation and of signaling are, perhaps every bit as important as the airplane itself. Instruments for indicating speed, direction, height, distance travelled, etc., have all required extended and careful research by the Physicist in all airplane work, whether in observations or in making attacks, it is necessary for the men in the machines and the men on the ground to be in constant communication. The wireless telephone is the obvious solution. Wireless telephony has no doubt made more progress in one month of war than in one year of peace. The modifications and improvements made in wireless telephony apparatus in America’s physical laboratories by her scientists (most of which have as yet not been disclosed), have made the present world, which is positively epoch-making. Our improvements have made it possible (Con. on page 926).
Popular Astronomy

The Planet Earth as Others See Us

By ISABEL M. LEWIS
OF THE U. S. NAVAL OBSERVATORY

Were it possible for us to view the heavens from the planet Mars we might see in the hours just following sunset or preceding dawn a most beautiful star of first magnitude rivaling and at times surpassing the great star Sirius in brilliancy, closely attended by a small companion star considerably less brilliant. The smaller body is evidently a satellite of the brighter one, as its position relative to the larger body changes in such a way as to show it is revolving around it. It appears now to the east, now to the west of the chief star. At their widest separations the two form a very distinct double star, unique in the heavens of the Martians. As the little star travels from one side to the other of the bright star it usually goes above or below it the occasionally it passes directly in front of or behind the brighter body and at such times only one star is then visible to our Martian observers.

This lustrous double star, the morning or evening star of the Martians, is our planet Earth and its satellite the moon.

Were we observing our planet from Mars it would be quite beyond our powers of imagination to conceive that this tiny point of light, glowing by the reflected light of the sun, has been for ages upon ages the abode of species and forms of life of well nigh infinite variety that have existed under widely different conditions of temperature and pressure not only on the surface of the planet but in the depths of the seas that cover three-fourths of its surface.

We can imagine conservative scientists of Mars frowning at the flights of fancy of the Martians in regard to the nature of the inhabitants of this other world in space. Yet in their wildest speculations the Martians could hardly exaggerate the wonders of our planet Earth or the strength of the conflicting forces for good and evil to be found upon it.

Let us consider for a moment how our planet Earth and its satellite would appear were we able to examine it telescopically from Mars. Most of the difficulties that beset us here on earth in our attempts to observe Venus telescopically would be experienced in attempting to view the planet Earth from Mars. A reference to Fig. 1, which shows the relative positions of the three planets, will make this clear. The earth's orbit lies between Mars' orbit and the sun, just as the orbit of Venus lies between us and the sun. As we will see later, Venus has a decided advantage over Mars for observations of the planet Earth. On Venus and on our own planet, Mars can be seen in opposition to the sun that is on the Meridian at midnight, with its disk fully illuminated like the full moon. To Mars, on the contrary, all the inner planets, Mercury, Venus and Earth, appear as half or crescent moons telescopically when they are in the best position for observation and they never appear with fully illuminated disks.

When the earth is nearest to Mars, in position Eo, see Fig. 1, it is invisible to the Martians, just as Venus is invisible to us in the corresponding position, owing to the fact that it is then in line with the sun and lost in the glare of its light. This position is known as the planet's inferior conjunction with the sun. Just before and after the earth is in this position it would show a very thin crescent if viewed telescopically from Mars.

In the position E, the earth is once more in line with the sun and Mars in what is
known as superior conjunction, and is again invisible. Just before and after it is in this position its disk is like a gibbous moon almost entirely illuminated, but it is unfavorably situated for observations from Mars because it is so near the sun and on the far side of its orbit from Mars. In position E₁ and E₂ the earth is at its greatest distance from the sun, spoken of as its greatest eastern and western elongations, as seen from Mars. It is then a half-moon in the telescope, is at its highest elevation above the horizon and is evening or morning star to the Martians, according as it is east or west of the sun. We might expect that it would now be in its most favorable position for observation, but this is not so.

Looking at Fig. 1 we see that as the earth passes from the position E₁ toward inferior conjunction with the sun at E₂, its distance from Mars decreases and therefore the apparent size of its disk increases. The form of the illuminated portion now changes from half moon to crescent but the total area of the illuminated portion increases up to a certain point. When the area of the illuminated portion of the planet has its greatest value the brilliance of the planet is at a maximum. The exact time when this will occur can be worked out mathematically. The best observations of the earth seen from Mars would be obtained when the planet is in this position and the corresponding one lying between inferior conjunction and western elongation. (See positions E₁ and E₂ in Fig. 1.) We can therefore imagine the Martians observing our planet at its best in the morning or evening twilight. The brilliance of the earth in Martian skies at this time usually surpasses that of all other planets. Mercury and Venus, the also evening and morning stars to the Martians, appear considerably less brilliant than they do to us. The earth appears to the Martians much as Venus does to the earth, the less brilliant, owing to the fact that Venus comes nearer to the earth than the earth does to Mars. The only planet that may rival the earth at the time of its maximum brightness is the giant planet Jupiter, which appears at times brighter to the Martians than does our own planet.

In their telescopic observations of the earth the Martians would experience the same difficulties that we experience in our observations of Venus. When the planet is in its most favorable positions for observation the greater part of its disk is darkened, owing to the fact that the phase is the same as that of the crescent moon.

The Martians, however, would not be handicapped by a dense cloud-laden atmosphere such as surrounds Venus and makes it so difficult for us to observe. As the earth’s diameter is twice that of Mars, our observation of the earth viewed from Mars is considerably more extensive to the Martians than the markings on Mars appear to us, the drifting clouds and snow storms on our planet appearing to any other planet as mazzing as the Earth-Moon system does to Venus at the time of nearest approach. The brilliance of the earth seen from Venus at this time is twice that of Mars and appears to us at its best. As the earth’s disk is then fully illuminated the inhabitants of Venus have a great advantage over the inhabitants of Mars in their study of the surface markings of our planet. Objects on the earth’s surface only six miles in diameter can be seen easily by the inhabitants of Venus with the assistance of such telescopes as we employ for the observation of the planets. When Mars is most favorably situated for observation from the earth the diameter of its disk is between fifteen and twenty-five seconds of arc, according to its distance from the earth at the time of opposition. When the earth is most favorably situated for observations from Venus the diameter of its disk is sixty-three seconds of arc and that of the moon is seventeen seconds of arc. So even the disk of our moon appears at certain times as large seen from Venus as the disk of Mars seen from the earth. The markings on the earth itself seen from Venus stand out more distinctly as an object than the markings on Mars do to us at the most favorable opposition of Mars as we are nearer to Venus than to Mars.

It is when we take our station on our own little satellite, however, that we behold our planet earth as the ancients wished to consider it—the most wonderful and awe-inspiring object in the heavens. To the inhabitants of the moon, there were such the earth’s disk would appear four times greater in diameter and sixteen times greater in area than the moon’s disk appears to us. Since the moon, in its revolutions around the planet earth, always keeps the same face turned toward it, the position of the earth, for any one point of observation on the moon, remains immovable in the heavens. At various phases of its illumination by the sun the moon appears now to full the earth appears to the moon to pass from full to new and vice versa.

The rotation of the earth on its axis is plainly visible from the moon even to the naked eye. A distinctive marking will appear at the western edge of the earth’s disk, such as the Black Sea. It will be carried gradually eastward by the rotation of the planet and will finally disappear twelve hours later at the eastern end.

Oceans and continents and polar caps are visible in their general outlines and contrasting shades, visible easily to the naked eye. (Continued on page 911)
Radiophony to Airplanes a Great Success

A CONSIDERABLE time before the United States entered the world war the Bell Telephone system supplied the American Navy with a wireless telephone outfit designed for communication between an airplane and a station on land or on a ship. From that time on until this country entered the world-conflict, the Western Electric Company, as a part of its general study, conducted the work of perfecting light, compact wireless telephone sets, which would be available on small vessels and on airplanes. The first successful wireless test between an airplane and the ground after our entry into the war was made with one of the sets designed and completely built by this enterprising engineering organization prior to our entry into the war. The test was made on Langley Field.

On May 22, 1917, Gen. George O. Squier, Chief Signal Officer of the United States Army, sent for Dr. F. B. Jewett, chief engineer of the Western Electric Company, to confer with him with reference to the matter of equipping airplanes with wireless telephone apparatus. At this conference, which was held in Washington, besides Gen. Squier and Dr. Jewett, there were present E. D. Craft, one of Dr. Jewett’s principal assistants; Capt. Col. C. C. Culver, of the Signal Corps, and Col. Rees, of the British Army Air Service. The possibility of providing airplanes with wireless telephone service was discussed, and the reports of the development work being done by the Western Electric Company made by Dr. Jewett were so promising that he was ordered in writing by Gen. Squier to proceed with the development of the system, and to actually equip ‘planes with it.

The Bell system engineers had progressed so far at that time that they were able on July 1, 1917, five weeks after the first conference, in a test at Langley Field, to actually demonstrate the working of the wireless telephone between an airplane and the ground. This test also showed that it was practical to operate the system between two or more airplanes in the air.

“All this sounds very simple, but it would take volumes to describe the innumerable experiments and heart-breaking failures before the first real successes. So far as the radio part of the equipment was concerned we had an answer in a short time. We had developed some very successful forms of vacuum tubes and it was a simple matter to assemble them with the necessary coils, condensers and other apparatus that comprise the transmitting and receiving elements. Working this apparatus under ordinary conditions on the ground, and in a swift-moving and tremendously noisy airplane, were two entirely different propositions. The noise of the engine and rushing air was such that it was impossible to hear one’s own voice, to say nothing of the weak signals of the telephone receiver,” stated Edward B. Craft, Assistant Chief Engineer of the Western Electric Co.

One of the first problems was to design a head set which would exclude these noises, and at the same time permit of the reception of the telephone talk. A form of aviator’s helmet was devised with telephone receivers inserted to fit the ears of the pilot or observer. See accompanying illustration of the helmet with ‘phones complete. Cushions and pads were provided for adjusting the receivers to the ears and the helmet fitted close to the face so as to prevent as far as possible, the sound being heard either thru the ear passage or thru the bony structure of the head, which acts as a sort of a sounding board. A helmet, such as that illustrated, was finally developed and was found to solve this portion of the problem. The earpiece finally adopted was made of sponge rubber (made so by blowing air thru it while molten), reinforced by tinfoil, and the receivers themselves embedded therein. These were mounted in a thick leather helmet, to be clamped over the flier’s head and ears. It effectually muffles bone transmission also, besides permitting the use of oxygen or gas masks.

Everyone knows how sensitive the ordinary telephone transmitter is to extraneous noises, and it does not require a wide stretch of the imagination to picture how this would act alongside the exhaust of a 200 horse power gasoline engine. A brilliant line of experimentation finally resulted in a form of a telephone transmitter or microphone, which possess the remarkable quality of being insensitive to engine and...
wind noises, and at the same time very responsive to the tones of the voice. With these two elements in hand, the problem was apparently solved. The fact remains, however, that three solid months of the hardest kind of work was necessary to iron out all the kinks and get the thing in shape so that it might be considered a practicable device for the everyday use of other experts, as Mr. Craft points out. The microphone perfected for this work has no mouthpiece, but instead a flat cap having three tiny openings about 1/16 inch in diameter. The voice waves pass thru these onto the diafram easily, but the engine noises swirl round it in other directions and do not enter in sufficient volume to be heard at all.

A typical performance of the radiophone between planes and ground will prove of interest. Here is the way it worked at one of the first official army tests at the flying field at Dayton, Ohio, December, 1917, as related by Mr. Craft.

"The planes left the ground and after what seemed to be an interminable length of time, we got the first sounds in the receiver, which indicated that they were ready to perform. The spectators were only mildly interested, and some seemed to be a bit bored. Suddenly out of the horn of the loud speaker came the words, "Hello, ground station. This is plane No. 1 speaking. Do you get me all right?" The bored expression immediately faded, and looks of amazement came over their faces. Soon we got the same signal from No. 2, and the show was on. Under command from the ground the 'planes were maneuvered all over that part of the country. They were sent on scouting expeditions and reported what they saw and heard thru the air. Continuous conversation was carried on, even when the planes were out of sight, and finally upon command they came flying back out of space and landed as directed.

Electric current must be supplied to operate the wireless set on the plane, as we well know, this current being used to heat the filaments of the vacuum tubes and to operate the transmitter. But the planes were already loaded down with all the gear they could carry, and the use of heavy storage batteries was out of the question. The airplane engineers would allow nothing to be connected to their engines, so there was nothing left but to supply a separate radio dynamo, and drive it by a wind propeller, taking its power from the rushing air. Airplanes are in the habit of flying at various speeds, and the specifications stated this to be from forty to one hundred and sixty miles per hour, the latter figure representing the speed when the machine was diving. The little dynamo, therefore, had to deliver a constant voltage with a speed varying from 4,000 to 14,000 R.P.M.

The microphone and receivers used for radiophoneing from plane to plane or plane to earth are arranged by means of a switch so that the pilot and observer can converse over the telephone circuit between the pilot and his mechanic with ease, and by throwing a switch can connect themselves with the radio apparatus and talk with the men in another plane or two miles away, or to the ground.

The primary object was to make it possible for the commander of a four squadron to control the movement of his men in the air, the same as a squad leader of infantry does on the ground. For this purpose extra long range is not required, and the distance over which they can talk is purposefully limited to two or three miles, so that the enemy cannot overhear, except when actually in combat, and then nobody cares.

The Navy also makes use of these sets in their seaplanes, and here the range is somewhat greater, up to twenty miles in some cases. The Navy has also made use of a modified form of this set in their 110-foot sub marine chasers. The chasers hunt submarines in packs, and by means of the radio telephone, their commanders keep in constant touch with each other, thereby greatly increasing the effectiveness of their operation.

Finally, with the formal demonstration completed, pressure was immediately applied to produce the necessary quantity of sets with their multitude of auxiliary and subsidiary parts. From January 1, 1918, to the early summer of that year the Western Electric Company established factories and trained thousands of operators to whom the armistice was signed the necessary transmitting and receiving tubes for radio telephone sets were being produced at a rate in excess of a million and a half good tubes per year. Improvement in vacuum pumps has resulted in a wonderfully high degree of exhaustion being attained—about one-billionth of an atmosphere.

Altogether thousands of radio telephone sets of different types have been manufactured and delivered to the Army and Navy since the early part of 1918. In spite of the fact that prior to July, 1917, no commercial types of this apparatus were in existence, and some of the fundamental problems had not yet been solved, the resources of this great telephone engineering organization were sufficient to establish on a commercial basis, within this short space of time, practically speaking, an entirely new art!—Photos Courtesy W. E. Co.

HOW AIRPLANES FIND THEMSELVES BY RADIO.

In his recent lecture before the American Institute of Electrical Engineers at New York Major-Gen. G. O. Squier, in connection with his description of the war's developments in radio apparatus, spoke as follows concerning the problem of aerial navigation:

"One of the principal problems of airplane navigation has been the evolution of a suitable compass, particularly for night bombing work. Magnetic and gyroscopic compasses have limitations at present which make impossible reliable air navigation by dead reckoning."

Do Radio Waves Travel Above the Earth or Thru It?

By DR. J.E. de FOREST

(Written exclusively for the Electrical Experimenter)

The editors sent a copy of the article published in the December 1919
issue of the Electrical Experimenter entitled "Radio Around the World," and also the editorial in that issue by Dr. H. Gernsback, covering several interesting and more or less doubtful theories concerning the propagation of these electric waves over a distance of 12,000 miles, i.e., between Carravon, Wales, England and Sydney, Australia. To Dr. Lee de Forest, the prominent American radio engineer and scientist. The editors asked Dr. de Forest the following questions:

First: What is your opinion concerning the etheric wave transmission above the surface of the earth, i.e., free space wave propagation?

Dr. de Forest: Do you believe that the etheric wave wireless transmission is better beyond the computed fifty mile atmospheric envelope surrounding the earth, and how far into interstellar space do you believe these signals might be carried? Imagine for the moment that an airship fitted with sensitive receiving instruments could have traveled away from the earth for any desired distance? Do you think these waves would be felt on the moon, approximately 238,800 miles distant, considering of course that suitable receiving instruments were available at that point?

Second: What is your opinion concerning the ground wave transmission, i.e., do you believe, with the geologists and others, that the earth presumably being a molten mass in the interior, might be a better conductor than the soil and rock crust surrounding it, and that this gaseous interior of the earth might therefore prove a better conductor than the soil and rock strata, and thus that the ground radio wave may have traveled directly thru the earth or a distance of nearly eight thousand miles—corresponding to the diametrical axis—or do you believe it much more likely that these ground waves followed around the curvature of the earth in the manner explained by Prof. J. Zenneck, and other investigators, each ground wave gliding over the surface of the earth?

Third: Is it your opinion that the present day that the pure etheric space wave, gliding over the earth in accordance with the generally accepted theories concerning radio transmission, is the predominating wave, both as to electrical energy involved and amplitude compared to the ground wave; or is the ground wave superior in its energy component and amplitude? These conditions are shown graphically in the following diagrams, Fig. I, and I would request your opinion on the relative extent above and below the surface of the earth, of the space wave and the ground wave respectively.

Unquestionably the molten interior of the earth would conduct low frequency oscillations with comparatively little loss, it is obviously impossible to make connection to this molten interior, ordinarily, and one cared to experiment with two volcanos at a comparatively short distance apart, making each crater the terminus of the current from the terminals of an A.C. generator, and at some distant point on the earth's surface between the two neighboring volcanos another parallel wire in which a tuning and detecting device was located, very interesting results might be obtained. See Fig. 2.

However, if such a combination could be found there would probably exist not the slightest excuse for sending telegrams between stations thus situated. Unfortunately or fortunately, we cannot look up to our volcanos as we would subway tubes.

If you imagine a powerful wireless station could be operated at a sufficient distance from the earth's surface, and completely isolated therefrom, remarkable distances of transmission thru the ether might be achieved, and the energy obtainable at the moon from a given output of energy transmitted near the earth's surface can be calculated, by inverse square law. It will be found that a tremendously powerful station would be required to transmit signals to any such distance. You doubtless are aware of the remarkable distances obtainable from airplanes equipped with comparatively small transmitters. Just recently an army airplane carried on radio observations fully over a distance of 150 miles. The distances are usually much greater than where a single receiver is located on the earth's surface, using a similar length of antenna.

The phenomena involved in such transmission, where the airplane is, say, two miles above the earth's surface, are doubtless complex. Here the ground wave is originally a free space spherical wave, but when the surface of this wave reaches the earth it doubtlessly cuts and the earth for a small depth and becomes then a true ground wave, originating from an earthed antenna. See Fig. 3. There for interesting data on the phenomena of transmission from airplanes, and whoever will collect and publish such data will be confering a great service to the Radio Art.

Concerning your question as to whether the wireless telegraph or travel or glide along the surface of the earth in the manner which I have described above, each wave having a grounded foot or base, generating a short distance into the earth, I might mention a very interesting phenomenon which we have encountered in installing wireless stations in mountainous or mining country in the western part of the United States. Figs. 4 and 5 illustrate this phenomenon. Fig. 4 shows a case which often happens in the early commercial days of radio telegraphy, and where a grounded forest or other party wished to install a station in a valley or cleft, which happened to have sharply rising cliffs on either side. Apparently thecomprehended sky, and the ground waves became so stretched out or attenuated on the earth's surface, the effort to leap across this valley, that the station was only able to intercept a very weak signal or no signals at all. It was found advisable in this case.

Various Phases of Gliding Wave Wireless Transmission Used in Discussion Here Given. In General, the Etheric Space Waves Above the Earth, Accompanied by its Grounded or Foot Wave.
Aerial or Ground Radio—Which

The Opinions of Two Leading Wireless Experts

Do Radio Waves Travel Above the Earth or Thru It?—by Dr. L. W. Austin, Radio Expert, U. S. Naval Radio Laboratory.

REPLYING to your queries of recent date, I am very glad that you have asked these questions and will answer them to the best of my ability.

Q. 1. I see no reason to doubt the validity of the old theory of wireless telegraphy which supposes a wave in ether (and under certain circumstances in the upper layers of the earth, provided they are sufficiently bad conductors), the lower ends of the electric lines being grounded on the conducting surface. The space wave under most circumstances carries the greater part of the energy, except where the wave front is bent very far forward. This theory, it seems to me, is sufficiently proven by quantitative observations on received radio current which at moderate distances always agree within a few per cent with theory. It is true that the antenna produces a field corresponding to a Hertz oscillator of twice its length.

Q. 2. I believe that the currents in the earth are only incidental to the presence of the ether waves.

Q. 3. In the case of transmission between stations and the earth, the phenomenon is similar. In sending from a plane, the wave must start as a plane ether wave which spreads downward and grounds itself, and then spreads out longitudinally (with a more or less bent wave front) very much like the wave from a grounded antenna.

Q. 4. In antennas close to the ground or buried in the ground which, by the way, behave entirely differently from the higher ones, the wave penetrates much more deeply into the earth. Hence, in static-signal reception, the reception is accomplished by picking up the earth currents produced by the wave. These, of course, become relatively more powerful at greater distances from the sending station, owing to the usual bending forward of the wave front. The sending from earth or buried antennas is probably accomplished as follows: The first place, ground currents on the earth are generated by an electric field in the ether above the earth's surface. This field in spreading over the ground gradually rights itself and travels off very much like the field from an antenna, except that it is directional.

Q. 5. I do not believe that it is probable that any wireless radiation passes thru the Heaviside layer. (Ed. Note: This would seem to eliminate the "Mars" radio story which has been going the rounds of the daily press."

Q. 6. Experiments indicate that long waves can be detected at greater depths than short waves, as would be expected from the ordinary skin effect phenomenon of alternating currents.

I am very sorry I have to disagree with Mr. Tesla in this matter, for I consider him the father of wireless telegraphy. His lectures in the early '90s contain full development of connection of a wireless system to anything which we actually had in practice before 1910, except for the lack of a proper detector.

How I Believe Radio Wave Transmission Is Accomplished

By F. H. KROGER

Chief Engineer, International Radio Telegraph Co., Formerly Chief Engineer, National Electric Signaling Co.

In response to the request of the Editors of the Electrical Experimenter, for a bit more fulness with regard to the questions here submitted:

Q. 1. Practically all the energy delivered by the radio transmitter is radiated in the form of waves gliding on the earth's surface. Any energy which may be found to exist in the earth's surface is supplied by the waves sent out from the antenna. The power the conductivity of this surface, the more energy is taken from the wave, and consequently the less there is available at the receiving station.

Q. 2. There must exist in the earth's surface, currents at the feet of the waves referred to in question number one. Means for detecting these currents will give a method of receiving messages. These currents, however, represent only a small per cent of the energy of the traveling wave. It is quite generally agreed that the wave above the surface cannot exist without the current in the surface and vice versa.

Q. 3. Yes.

Q. 4. Currents due to the gliding wave.

Q. 5. The "Heaviside" isolation layer must be a spiral wave. One of the explanations of the marvelous work done in the North during the winter is the fact that the ionized layer of the Aurora, coming close to the earth, provides a boundary to the waves which prevents the usual attenuation.

Q. 6. The ground losses are higher with longer wavelength for poorly conducting earth, in the vicinity of the antenna, which indicates that a greater volume of the earth is affected by the currents. This greater penetration would also hold for the gliding wave. Ground tests made some years ago indicated that the ability to receive signals did not depend upon the quality of the ground nor the wave-length; therefore Mr. Rogers' system probably does not depend upon a penetration due particularly to long wave-lengths, but upon a penetration which is sufficient for his purposes, given by any wave-length.

EXAMINATIONS FOR AMATEUR FIRST GRADE RADIO OPERATOR'S LICENSE AT NEW YORK

Examinations for amateur first grade radio operator's licenses are being given at Room 603, Custom House, Bowling Green, New York City, every day after 9 a.m., by Mr. Guthrie, Chief Inspector of that district.

Attention is called to the fact that applicants for amateur first grade radio operator's license must qualify in the transmission and reception of Continental Morse code at the rate of ten words per minute instead of five as formerly.

Papers covering these examinations will be rated by the examining officer as soon after the examination, as possible; but no licenses will be issued until amateur stations are permitted to operate.

Please Note: By taking this examination authority is not granted to open your station. It will be necessary after the examinations are authorized to open, to furnish on form 762, Applicant's Description of Apparatus, the particulars required and await the issuance of station license as well as the operator's license before operating the station. Form 762 is to be filled in and filed until the station has been made ready for operation, as it is important that the exact dimensions of the antenna and the place of power to be used be stated in this application.

You are hereby cautioned that it is unlawful to operate an unlicensed station, and all amateur licenses (operators' and stations') issued prior to the war are now void.

When authority is granted to issue amateur license, a station license number and call letters will be given.

CHAS. D. GUTHRIE,
Radio Inspector.
The How and Why of Radio Apparatus

By H. WINFIELD SECOR

No. 11. How to Make and Use a Direct-Reading Wave Meter and Decrementer.

From time to time we will describe one particular instrument used in either the radio transmitting or receiving set, explaining just how it works, and why. We have received so many requests from new readers asking for such explanations that we have decided to publish this matter in serial form. In the course of several issues all of the transmitting and receiving apparatus will have been covered. The subject for the present number is HOW TO MAKE AND USE A DIRECT-READING WAVE METER AND DECREMENTER.

The present time seems an opportune one for the radio student and the radio amateur to prepare for the forthcoming opening of experimental radio opportunities, and we believe that no better use can be made of the spare time than to construct and study the use of the wave meter and decrementer. The accompanying text and illustrations show how to build a home-made wave meter which will give very satisfactory service. The dimensions given for the various parts of the instruments are taken from an experimental one which was carefully calibrated for the writer.

We will first take up the construction of the wave meter and will afterward consider the calibration curves to be used with it, and also the determination of decrement.

Perhaps the first part of the student's set that will come to hand as the student begins to study the building of it, is the inductance, or rather the inductances. These coils are also referred to as the exploring coils or exploring inductances. They are used to pick up sufficient energy from a radio transmitter or receiving set so as to cause oscillations to be set up in the wave meter circuit, which will be of sufficient strength to give a positive indication of resonance or non-resonance of the circuit, and thus to determine the exact period at which the current being measured is oscillating. The illustration, Fig. 1, gives the details of construction for the three inductances used with this wave meter. The wooden forms on which the coils are wound are best turned on the lathe from some fine grained hard wood such as mahogany or maple. The physical dimensions of the forms are given in the drawing and the specifications for building these coils must be rigidly adhered to. Where the accuracy of the instrument within a few per cent below or above the calibrated values is not imperative, No. 20 gage magnet wire, covered with a single winding of silk may be used; but due to the peculiar qualities of enameled magnet wire and the number of turns per inch of winding, etc., it will be seen that the specifications here given should be carefully followed to obtain the inductance values in centimeters here given. The three coils, numbers 1, 2, and 3, have inductances of 36,000, 120,000 and 259,000 centimeters respectively.

The manner of attaching the inductance coils to the wave meter cabinet is shown at Fig. 1, and consists of two lugs made of 1/16 inch brass and having slots at the lower ends of each. This enables the operator to slip the coils on and off the binding posts quickly. The inner and outer leads from the winding of the inductance should be carried thru diagonally drilled holes in the wooden form, as is indicated by the dotted lines, and they should be soldered to the two brass lugs, which are screwed to the form of a small flat-head brass wood screws. The wooden form may be varnished or shellacked before winding, but the winding itself should not receive any coating of shellac or varnish, as this changes the distributed capacity of the coil. Do not use any iron in building these inductances.

The next item calling our attention is the variable condenser, and we might say a great deal concerning this part of the apparatus, and then again we might just as well say very little. Experience dictates that this comes out about as follows: in the first place many radio experimenters would rather obtain on the market a small rotary type variable condenser having the proper capacity for use in this particular wave meter, and this should be .0086 microfarad. Of course any condenser having this capacity within a small fraction one way or the other may be used, but if the student wishes to have a good accurate wave meter, and intends to eventually have it calibrated or checked against a standard wave meter, then he will do well to select a good sturdy and reliable make of rotary condenser. Some of the points to be watched in the design of such a condenser are that it should not have the rotary and fixed plates too closely spaced, or else it will frequently give trouble by short-circuiting; the rotary plates should be accurately locked on the rotary shaft either by having their hubs molded on the shaft or else they should be mounted on a square shaft so as to turn, and again they can be keyed on the shaft. For the purpose of a wave meter there should also be practically no up and down movement or play in the vertical shaft supporting the rotary plates. For all practical purposes, the capacity of a rotary variable condenser (see Fig. 2) is determined by the usual capacity formula using a K value of 1, which is that for air.

Many radio amateurs and experimenters

Dimensions of Home-made Variable Condenser of the Required Capacity for Wave Meter Here Described.

[Diagram of wave meter and its components]

[Diagram of variable condenser and its components]
will undoubtedly wish to construct their own variable condenser having this required capacity, and the physical dimensions of such a variable condenser are given in Fig. 2. As will be seen, this particular design comprises three stationary and two rotary aluminum or brass plates. These plates should preferably have a thickness of 1/16 to 3/32 inch so as to be perfectly flat and retain their shape and thus maintain the accuracy of the condenser when once assembled. The four active air dielectric spaces between the plates should be exactly 1/32 inch. The diameter of the rotary plate, as Fig. 2 indicates, should be 8-23/32 inches, and by cutting the lugs on the stationary plate as well as on the rotary plate in the manner indicated, will permit of the accurate interleaving of the rotary and stator plates so as to give the proper capacity.

Thus we see that the two principal parts of any wave meter are—an accurately calibrated variable precision variable condenser and an accurately calibrated dial. In practically all cases this inductance and capacity of known values are connected together in parallel or shunted as shown at Fig. 3-A. Referring to Figs. 3-A and 3-B, the lead wires joining the inductance or exploring coil to the variable condenser are composed of two pieces of No. 10 flexible lamp cord, each 6 inches long. A 3-inch length of copper strip joins the two pairs of binding posts. The third wire is a binding post being used for the inductance coil and the other set intended for the connection of a hot wire milliammeter or thermocouple and galvanometer. Ordinarily this latter pair of binding posts are fitted with a piece of copper strip about 1/16 inch thick forming a jumper.

It is well in all cases to fit a safety spark gap across the terminals of the variable condenser as shown at Fig. 3-B, as when the wave meter is used in close proximity to radio transmitting sets, there is very often a sufficiently heavy current induced in the wave meter circuit to cause a puncture of the insulation of the inductance coil or a short-circuiting of the variable condenser, especially if the latter happens to have closely spaced plates.

For indicating the maximum resonance when measuring the length of a transmitting set, where the induced current in the wave meter is of course quite strong in any case, a very good indicator, as proven by practical and experience, is an ordinary 3-inch Geissler tube, or better yet a small helium gas tube. It is best when using either a Geissler or helium tube as an indicator of maximum resonance, to place the tube in a small box mounted on the lid of the wave meter, the box being blackened inside and provided with a slot in the front so that the degree of glow in the tube may be easily seen. It is also common practice to connect a hot wire milliammeter in series with the inductance and condenser of the wave meter by removing the jumper on the series binding post terminals and connecting the meter to this; in this case the maximum resonance, and therefore the wave length at which the circuit under test is oscillating, is indicated by turning the condenser handle until the needle of the hot wire meter reaches a maximum reading. Some operators prefer to use the well-known detector and telephone receiver method of determining the resonance point in the wave meter circuit as the diagrams in Fig. 3 show. The detector and wireless 'phones are connected in series or in multiple across the variable condenser for the purpose. This arrangement is extremely sensitive, and one invariably used in measuring the wave length of received signals. The Geissler tube or other apparatus is, of course, disconnected from the wave meter circuit, if the detector and phone method is to be used. With respect to the detector used on the wave meter, it may be said that either carboniodum or iron pyrites proves best, as either may be subjected to a very strong current without harm.

Figures 4 and 5 show two more circuits used with the wave meter. Fig. 4 shows a detector and telephone receiver circuit, connected to the main oscillating circuit of the wave meter by a unilater or one-way connection. This method is highly recommended in many text books treating on the wave meter and its uses, and at the present time it is used on many of the best commercial wave meters. This connection of the detecting circuit possesses the advantage that it cannot have any detuning or offsetting effect on the oscillating circuit as is the case where it is placed in shunt to the capacity and inductance composing this circuit, and it is very efficient for the purpose in hand, as with this connection the detector and phone receive just a sufficient amount of energy to operate.

(Continued on page 921)
German Radio Apparatus Used at Metz

THE accompanying illustrations show the interesting radio apparatus and antenna mast used at the famous German military base at Metz. These photographs were taken by the French Army when they entered Metz after the signing of the armistice. The photograph of the aerial mast is interesting as it shows a novel construction whereby a strongly braced tower structure is formed of steel cables or ropes, provided with ducted ends thru which bolts are past. The base of this radio mast, measuring 80 meters in height, is tapered to a point at the bottom, as the photograph shows, and rests on a large porcelain insulator. Suitable guys and pins were used in arranging this insulating base support, so that the foot of the mast could not slip or break away if for any reason the insulator should break. The mast was well guyed with steel cables running in different directions, and the antenna was supported in umbrella fashion from the top of the mast. As the photograph discloses, a high steel fence enclosed the grounds connected with the station to preserve secrecy, and also to prevent any one coming in contact with the highly charged aerial conductors.

The remaining two photographs show respectively front and side views of the receiving apparatus used at Metz. One of the first interesting things we note in connection with the design of the apparatus, and plainly visible in the side view is the rotary control of the inductance slider. This is accomplished by a lever secured to a rotary knob, the free end of which is joined by means of a link member to the slider of the inductance in the manner shown, so that as the handle is turned in rotary fashion, the slider will move back and forth along the coil. The detectors, of which there are several in duplicate, are observed at the top of the instrument, while an elaborate multiplicity of control handles with graduated inductance pointers, are provided for changing the wave length of the primary and secondary receiving circuits, as well as the coupling between the coils of these circuits, and also the capacity values used.

The telephone receivers, several sets of which may be used when desired, are connected with the receiving set cabinet by means of flexible cords and jacks, eight of which are placed in a group at the lower center of the front panel.

Among other things, we find it interesting to note the very neat arrangement of the interior wiring of the cabinet, the various connections being run symmetrically in straight lines, evenly spaced and held rigidly in place by means of insulating cleats. In the side view of the apparatus, which shows the interior, one may perceive the nearly wound inductance coil at the bottom of the cabinet, and as will be seen, it is square in form with a number of inductances placed along the form on which it is wound. This set is designed so as to be suitable for receiving either spark or arc signals. No cleaner, being as a vacuum is always clean? And whether undamped waves oscillate or vibrate? Whether it would be murder to kilowatt? And whether you can measure water with a wave-meter? And how a bus-line can run from place to place without moving? And whether it would be nice to be a miner in the mines of Asia Minor? And if a condenser is over charged by a conductor would it cause a disturbance on the trolley line? And where does the dogo when nite approaches? And how to tell when onion plants armature? And what is the price of a drink at the bus bar? And why some books persist in saying a.c. current and d.c. current instead of a.c. and d.c.? And whether there are any seeds in a transformer core.

CHAIN OF RADIO STATIONS.

The establishment of a chain of radio stations, approximately 30 miles apart along the Atlantic Coast, was announced at the headquarters of the 1st Naval District recently. The statement intimated that by this arrangement incoming vessels, when 150 or 200 miles off coast, could determine their position easily by communicating with shore stations, regardless of weather conditions. Along the 250 miles of coast included within the 1st District eight stations are already in operation.

COAST GUARD STATIONS TO HAVE WIRELESS.

In the near future radio stations will be installed at the coast guard stations at the Isles of Shoals, at Station No. 2 at Cross Island, Buck’s Harbor, Me., and Station No. 8 at Damiscove Island, Boothbay Harbor, Me. A number of radio operators will be sent to these stations.
A Timely Reinforcement
A Copper Plated Stomach

By THOMAS REED

THERE'S a lot in being forehanded. Mother was that way. Every Saturday we used to have salt fish for dinner, so she wouldn't be bothered with getting up anything to eat on baking-day. That sounds like a paradox, but, wasn't it, a shame, for the "baking" was very appetizing and savory, while the fish was—well, not so savory.

Now, when you wanted salt fish on Saturday, you had to begin way back in the week somewhere. Tuesday was a good day because there wasn't much of anything to do (so just the regular chores) except the ironing, and you had a chance to think. Follow me carefully—you know how long it is to go to work and separate the fish, and then had up with cooking formulas, and would need an accommodating sized pot to cook the fish could of been most anywhere without hurting it, so tell us children to go to it and forget the whole business. On Tuesday she commenced deodorizing the fish. You see, while the fish abode with the grocer, it was always picking up scents like coffee and spices and matches and kerosene, from the clerk's habit of wiping his hands on it in passing, and the hostler would chuck a horse-blanket on it often enough to give it a quaint stable tang. But what you called the basic flavor was imparted by "Tabby"—the store cat. The pile of codfish was the place where the cat slept and took her bath (the kind of dry-cleansing a cat calls a bath); also her refuge from stray dogs—or ambush, according to whether she could lick the dog or not. The result was you couldn't say the cat smelt fishy, or the fish catty, but they smelt about alike! It was a blend, like this fancy-named toiled water you have to have pronounced for you, can do something or other.

If you are interested in the fish for a smoking fish, you didn't have to do anything to it, it was all right as it was. But when you wanted to use it for an eating fish, you had to do just about—the fish part from the odor part, or as much of it as you could. It wasn't difficult or laborious at all, but it took time, and that's why you had to be forehanded. You put this fish into a good stout pan—a pan that wasn't particular whom it associated with—and covered it with cold water. The water didn't stay that way very long. In a few hours it was most unaccommodating, yellowing to heaven and casting into the air bunches of assorted perfumes, like Springtime tripping o'er the lea and scattering flowers—I mean the operation was the same, not the raw material.

When one dose of water had suffered about enough you poured it off and renewed it, and so on. If you tended right to your business thru Tuesday and Wednesday and Thursday and Friday and Satur- day morning, then by Saturday noon there was your fish—transformed into a regular eating fish—at least those who had to eat it could. That's how you had to plan meals in those days—no fretting away your time at tea-downtoons till the last minute, and from that moment nothing was thought of but comebacks to hand to Germany in return for her favors—about 40 years, with the accent on the last 4—which was righto, and success to the job; but in the rush of business, a very important point was overlooked by everybody but ME. I'll tell you what I mean.

You know how thick and fast the celebrations came, along there in November? They made a record, you know, and but that won't be beaten till "Bill" gets back from Hell. There was the "Fake Peace Celebration" on Monday, the "Real One" on Monday, and the "Regular One" on Tuesday. I don't know how it was with you, but by "Home" itself, the one with the good thought—and it was the only kind of food I was able to sit up and take.

The thought, being fed, was mainly to the effect, how nice it would have been if I'd had one of those dinners that are always being talked about and never realized. I don't know as I ever appreciated before how in a copper boiler is. Viewing the ruin of my faithful Gastric Cavity thru handling the few easy objects I'd sent down to it, I envied the old copper boiler at home—how it used to digest 3 or 4 bushels of the family wash, or boil up a barrel of soft soap, or a tub or two of whitewash-stunts really exacting, you know—and get away with it year after year.

Ah me, as the fellow says. With a tummy built on the lines of that boiler, one could celebrate Peace till the cows came home with their 16-cent milk, and then tackle a New Year's Eve and a couple of "wakes" on the side, instead of rueing the day—whatever that is—as I was doing.

But the real horror of the situation was this: here were a million or two of soldiers and sailors and meekly go thru this celebration—thing multiplied to the hundredfold-power. The big cities were going to send out—then the smaller branch cities, and the railroad towns, and the home towns—the strain all the time increasing as the burg grew smaller—till finally they'd fetch up the Big "H", with Mother roasting chickens and frying flapsjacks and baking pies in a wild effort to make up a year's deficiencies in army rations all at one meal. All that, and only an ordinary membranous stomach to stand it! Was there any time to lose? No. The copper-plate stomach, so long post-poned, had to be invented tout de suite if it was going to be ready for the occasion.

Well, here it is, all ready and waiting. (Continued on page 927)
The Alkaline Storage Battery

By J. F. SPRINGER

STORAGE batteries are of two principal kinds—(1) the lead-acid battery, and (2) the alkaline battery. Our attention is now directed upon the latter. There is but one alkaline cell of prominence on the market—the Edison battery. Each cell is a complete self-contained unit and may be used alone or in conjunction with other cells. A typical cell will have a voltage of about 2.0 average discharge potential; the maximum discharge potential is about 1.45 volts at the start. The charge and discharge voltage characteristics are given in the accompanying graph, Fig. 1. While charging the cell voltage may rise as high as 1.85 volts. The amperage will vary with the size of the cell. By connecting a battery of cells in series, it is possible to run the voltage up to any desired point; see Fig. 2-A. A usual voltage for rather short circuits—under 300 feet—is 30-32 volts. Accordingly, about 30 cells are required. The battery used as a unit will have the voltage equal to the sum of the voltages of the individual cells. The amperage will remain the same as with the single cell. It is necessary, therefore, to choose a size of cell that will give the amperage required for the service or else use more than one battery. Connecting the batteries—not the cells—in parallel, see Fig. 2-B. For a 110-volt system, a large number of cells will be needed. In making such calculations, it will be best to rate the alkaline cell at just about 1 volt. Thus, for 110-volt service use 110 cells, connected in series.

In purchasing a battery, it will be necessary to decide on the voltage to be used. There are probably more household and similar devices on the market that are designed for the 110-volt system than for any other. At the same time, there is a considerable range of such devices which are adapted to, and available for use on 30-32 volt circuits.

The alkaline cell has a tight-fitting cover. As in all batteries there will be generated a certain amount of gas; this escapes thru a special valve. The cell is well suited to rough usage, partly because of the tight cover and partly because the container is of sheet steel and not of glass or hard rubber. The liquid is of an alkaline character. It

---

**Diagram Showing Voltage and Amperage With Series and Parallel Connections of Battery Cells.**

A. Cells connected in series. Volts = A x number of cells; volts per cell; amp-hour capacity X A x num. of cells.

B. Cells in parallel. Volts = 1/2 x volts of one cell, amp-hour capacity = A x Amp. Hour Capacity of cell, number of cells.
Experimental Mechanics

BY SAMUEL D. COHEN

LESSON XI

THE THEORY OF TWIST DRILLS.

The student who has been following the past lessons in "Experimental Mechanics" now finds himself confronted by a more or less difficult task in properly utilizing a very important tool, namely—twist drills, and thereby is presented with the subject of twist drills and their grinding. Because it is very essential to follow understandingly the subject of twist drills, a short mathematical treatise of simple nature will be given in order to more readily facilitate the understanding of the subject.

The twist drills stand in use so far above flat drills that they are now an indispensable tool in every workshop for metal working. They may be manufactured by milling or forging two spiral grooves out of a cylindrical bar, or by twisting a bar of the desired cross-section, so that the lines originally running parallel to the axis become spiral lines. The first method of manufacturing is today still the most common one. When we take a spiral drill and turn it with the top towards us, we shall see it as shown in Fig. 1. d are the spiral grooves, cc both cutting edges, so that the drill will have to turn in the direction of the arrow, cc is the solid part of drill; the top of the drill nearest to us is the edge c', which unites the two edges cc, making an angle of about 55 degrees with each of them. The cylindrical surface of the drill at ss, only exists for the part aa, for, to prevent unnecessary friction against the walls of the hole, the top of the surface is brought to a somewhat smaller diameter. Sometimes the surface cc is gradually laid off, beginning at the edge without a distinctly perceptible step, as in Fig. 1. The profile of the grooves dd, is chosen so that the intersection with the top plane b, gives as far as possible a right angle line c. The shape of the line c is of lesser importance provided that the groove d is wide enough to allow the chips to pass easily. The dimension of the weakest point of the drill where the edge c' is found, is fixed by the demand of strength in the drill. The edge c', which cuts very badly, should be as short as possible. Ordinarily, it is taken 1/10th of the diameter at the point of the drill and gradually increases to the upper end, for reasons of strength.

When looking at the drill sideways we now see it as shown in Fig. 2; cc are the sectants which form together an angle of about 120 degrees, c' the connection, dd the grooves, the pitch of which amounts to 5 to 8 times the diameter of the drill. We consider cc as being the cutting edges of two chisels, which, turning around the axis must cut chips from the metal. The form and the position of these chisels in regard to the metal will have to answer the same requirements as every other cutting chisel, which are these: In Fig. 3 A represents a cross-section of the chisel, B the piece of work from which the chip C is cut by moving A in the direction of the arrow.

To prevent the chisel breaking its cutting edge—the angle c—obtained by grinding, and therefore called the grinding angle, must be sufficiently strong. For cutting mild steel and iron c is made upon an average of about 55 degrees; with very good steel the angle can be somewhat smaller; with a poorer grade steel it must be somewhat larger. The loosening of the chip from the metal is not done at the lowest point of the chisel, but at a, being the point most advanced. The metal is pushed down at a length l, Fig. 3, and therefore returns to its level a-d. The smaller the angle i, which may be enlarged or diminished by the position of the chisel, the longer l will be, and the greater will be the resistance of the metal being pushed down. Experience tells us how large the angle i must be; it varies between 4 degrees to 8 degrees for lathe and planer tools. We shall see how great it must be made for twist drills. In no case may it be smaller than 4 degrees, or the chisel will refuse to cut.

Referring to Fig. 4, the point a, of the cutting edge c, situated on the cylindrical surface of the chisel, we find the grinding angle a, appointed by the tangent to the spiral and by the tangent to the line sectant of the cylindrical surface of the drill, and the ground top B. So the size of this angle is determined with regard to the strength of the edge and practically amounts to about 55 degrees. Then follows the angle i in Fig. 3: where to find it. While turning around on its axis the drill advances into the metal. So each point describes a spiral line with the pitch equal to the feed of the drill for one revolution. These spiral lines, however, are of unequal diameter. Point a, in Fig. 4, on the circumference of the drill is given in Fig. 5, as if moving on the spiral line da. The diameter of the drill being D = 1 in, and the feed 1/50th in; the inclination of the spiral line is found by:

\[ \tan \beta = \frac{1}{50 \times \pi} = 0.00637 \]

In Fig. 5 the value of the feed has been given immoerately large for the sake of clearness, and the angle \( \gamma \) has consequently been drawn much larger than it is in reality.

The spiral lines, da and ce, are the lines in regard to which the angle i, in Fig. 3, has to be measured. They are with the line a-d, in that figure. From this it follows that for point a of the drill the setting angle i is measured in regard to the line, inclining already 0° 22', and therefore must be so much greater than usually. For point c this difference becomes 3° 39'. The setting angle becomes a changeable value, increasing towards the center of the drill. In giving it everywhere the same value for simplicity’s sake, that is to say the largest cutting cross-section desired in the center, the edge would become too weak at the circumference.

With the above facts in mind the writer will give a complete practical discourse on how to handle twist drills, grinding, et cetera, in the next installment.

(To be continued)
Practical Chemical Experiments
Butter and Butter Substitutes
By ALBERT W. WILSDON

Butter is obtained by skimming the milk and putting it thru the process of churning, the globules coalesce and the solid fat separates more or less thoroughly from the other constituents of the milk. As found on the market, butter is rarely found to contain more than 80 to 85 per cent fat; the rest being principally water, with some proteins and lactose from buttermilk still remaining in it, and more or less salt or saltpeter, to flavor and preserve it. It quite frequently is colored with some harmless vegetable compound.

Oleomargarine is usually prepared from the fat contained in the intestinal folds of beef cattle. It is carefully stripped from the fresh carcass, washed, chilled and washed exceedingly fine. It is then rendered in water-jacketed kettles at a temperature of about 30 deg. C. The scum which separates out at the top is drawn off and the scaps settle at the bottom. The liquid fat is then run into vats and there permitted to stand for a day or two at about 27 deg. C., at which temperature butter is just liquid. The semi-liquid mass is then wrapped in cloths and prest to remove the thin yellow liquid oil (oleo oil) from the solid fat (oleo-earin). To turn this liquid oil (oleo oil) into a very good substitute for butter, it is churned with some milk so that it can absorb some of the butter taste, then some coloring matter is added (vegetable compound), and the mass is finally run into ice-water, thus chilling it rapidly. It can then be salted and packed like ordinary butter. Two marked advantages which this material has over butter are: (1) It is much cheaper, and (2) owing to the absence of buttermilk and butter fats it has much better keeping qualities. Its flavor ranks well with second-class butter.

"Renovated" or "Processe" butter is in general prepared as follows: Old, rancid, and unsalable butter is melted in a large vat surrounded by a hot water jacket at a temperature of about 45 deg. C. The curd and brine are then drawn off at the bottom, the scum being taken off at the top. Air is blown thru the mass, to remove the disagreeable odor, and after mixing with some milk, the mass is churned and then run into ice cold water to make it granular in structure. It is then ripened, worked to free it from buttermilk and salted. It is required by law in some states that this product be marked "Renovated Butter."

Simple Test for Butter
Experiment No. 1. See Fig. 1.

Heat about 3 grams of the sample in a large iron spoon over a low Bunsen flame, stirring constantly. Genuine butter will boil quietly, with the production of considerable froth or foam, which may, on removal from the flame; in the case of genuine butter these particles are small and finely divided, but in the case of oleomargarin the curd will gather in large masses.

Milk Test for Butter
Experiment No. 2. See Fig. 2.

To make a "milk test" for butter, place about 60 cc. of sweet milk in a wide-mouthed bottle, which is set in a vessel of boiling water. When the milk is thoroughly heated, a spoonful of the butter is added and the mixture stirred until the fat has melted. The bottle is then placed in a dish of ice-water, and the stirring continued until the fat solidifies. If the sample is butter, either fresh or renovated, it will be solidified in a granular condition and distributed thru the milk in small particles. If, on the other hand, the sample consists of oleomargarin, it solidifies practically in one piece, so that it may be lifted by the stirrer from the milk.

By the two tests just described, the first of which distinguishes fresh butter from process butter or renovated butter and oleomargarin; and the second of which distinguishes oleomargarin from either fresh butter or renovated butter, the nature of the sample examined may be determined.

Every house-wife should know how to test butter and oleomargarin and the important differences between them. That is one object of the present paper. The author trusts it proves of value.

(Continued on page 894)
A SIMPLE WHIMSHURST IN-FLICKER MACHINE.
By Melville Fisk.

The static machine described herein is made of simple materials, is easy to construct and the work does not require the use of special tools. A similar machine, built by the writer produces a violent and steady spark discharge about an inch or more in length, without the use of Leyden jars.

The plates are two-twelve-inch phonograph records of the disk type. Select two which have one side blank. The thin film sectors are cemented to the smooth side. It is not necessary to varnish the plates. The bosses that carry the plates parallel on the shaft are small cotton spools, that have a hole in them the size of the one in the record. Fit the spools up with brass tube bearing and fasten to the plates with glue. A thin cloth or paper washer inserted between the boss and plate will help the glue to hold. Rubber tire cement will hold better if at hand. The shaft on which the plates revolve extends out ⅝ of an inch on either side of the wooden standards; it is held stationary by a cotter pin inserted in a hole bored down thru the top of the standard. Glue a cardboard washer ⅜ inches in diameter to the inside of one of the plates. The base and standard are made of wood in the manner illustrated.

Make the double driving pulley from a large spool such as wire spool. Fasten it to the shaft by drilling thru the shank and shaft inserting a cotter pin or screw. Be sure and make the grooves in the pulleys deep enough to hold the belts securely. Rubber bands tied together make very good driving belts. Tie them with strong linen thread and leave a half inch of slack between each band. As the plates are to revolve in opposite directions, cross one belt.

The neutralizing rods are made from ¼ inch copper wire bent to shape. They are pivoted on the protruding ends of the shaft by a short piece of tubing soldered to the center. Press the tubing slightly together at the open end to make it grip firmly. The brushes are made by cutting a long copper strands secured from wire such as is used in receiver cords (gilt tinsel). Cut about twelve strands two inches long; tie a knot in the center, and fold over so that all ends are together. The brushes are then slit into the small tubes soldered onto the ends of the rods and are fastened by squeezing the end of the tube together.

Make the collectors as per sketch, using heavy copper wire. The points are long phonograph needles, fastened to the arms by drilling and then soldering. The needles should be slanted slightly in the direction in which the plate rotates. The supports are brass tubing, soldered on.

The discharging arms are of brass rod of a size that will fit in the collector supporting tubes. Make a small dent in each tube so that the rods do not slip all of the way thru. Fit balls to the ends of the rods by boring, then pegging and soldering.

The jars are used as supports only. Varnish them inside and out and fit with stoppers, bored to hold the collector tubes. A simple stopper is made by cutting a large wire spool in half and then winding paper around the shank to make a fit with the jar. Before using soak the stopper in melted paraffin. Further insulation can be obtained by placing pieces of a broken record under the jars. Glue the jars to the base.

In operation the neutralizing rods should be at right angles to each other, the best angle, however, can easily be found by trial. The brushes should touch the plates lightly—no pressure is necessary. The collector points should be about ½ inch away from plates. Be sure that they are all the same distance away or else some will not contribute to the collecting. The distance between the plates should be about ½ to ¾ inch.

THE FIRST PRIZE, $3.00
BLINKING LIGHTS TELL YOUR FORTUNE.

A glance at the illustration will show that while the magnet side of the relay is open, the small battery motor is running, revolving the drum. A gear may be used if a slower speed is necessary. When the push button is pre-stressed, the armature of the relay is attracted, breaking the motor circuit and making connection on the other side of the relay which goes to the one set of brushes on one side of the drum. The armature is itself connected to one side of the battery for the motor, and to one side of the current supply for the lamps. On the other side of the drum are the brushes connecting to the different rings on the drum. These brushes also connect with the various lamps which are again connected to the other side of the current supply for the lamps.

As the button is pre-stressed, the circuit thru one of the lamps is made, the particular lamp depending upon the position of the drum when the motor stops. Front of each lamp is a pane of glass on the back of which is pasted the fortune telling matter. The front of the glass may be painted with a thin white paint.

Contributed by WILLIAM F. HAASE, JR.

THE SECOND PRIZE, $2.00
PORTABLE BATTERY HAND LAMP FOR THE HOME.

The articles for the construction of this lamp can be purchased at a small sum, if you haven't them at home. Flexible lamp wire is the best for the wiring of this light.

About ten feet of wire is needed, when a large dry cell is used which cannot be carried around. For a pocket (flashlight) battery only a few feet is necessary. By means of the hook the lamp can be hung anywhere or in any corner on a nail, etc. A 1½ volt tungsten lamp is right for a single dry cell. A reflector adds greatly to the efficiency of the light.

A Simply Constructed Gas Generator

By IVAN CRAWFORD

Among the automatic gas generators on the market there are few within reach of the average experimenter. To meet this condition, Prof. C. D. Ditto has recently developed a generator which may be easily and cheaply constructed. In experimenting with qualitative analysis a constant supply of hydrogen sulfide is essential. This generator, being self-regulating, will furnish a constant flow of hydrogen sulfide, carbon dioxide, or hydrogen. The principle of operation is the same as that of the well-known Kipp generator, namely that when the gas formed is not allowed to escape the solid material is automatically raised out of the liquid, but when the pressure is relieved the solid substance is lowered into the liquid, and the generator begins to function. As will be seen in the drawing, the four parts are: first, a glass jar or container; second, a bottle of slightly smaller diameter, with the bottom removed, and fitted with a stopcock in the top; third, a lead basket for holding the solid material; and fourth, a small wash bottle.

The glass jar may be easily made by cutting off the top of a large bottle. There are many methods which may be employed in removing the bell of the bottle, but by far the best and surest is the one described below.

Several long strips of newspaper, about an inch wide, should be soaked in water and wound about the bottle in two bands at the place where it is desired to break the bottle. About a quarter of an inch should be left between the two bands. The bottle should then be slowly revolved with the bands, allowing a blowpipe flame to play upon the exposed part between the bands. When this portion is heated sufficiently the application of a drop of water will cause the glass to be evenly broken. The edges should then be smoothed on a soft grindstone. The bottom of the smaller bottle is removed in the same manner.

The sheet lead for the basket may be procured at any plumbing shop. It may be easily bent to the required shape, leaving small holes in the bottom to allow the acid to enter. The basket is suspended by means of a closed piece of glass tubing, bent to form a hook, which runs thru the two-hole stopper. The delivery tube from the bottle may be fitted either with a glass stop-cock or with rubber tubing and metal pinchcock. Altho not absolutely necessary, a wash bottle is a desirable addition to the generator, as it not only steadies the flow but cleans and purifies the gas.

The apparatus should now be assembled as is illustrated in the drawing and photograph. The solid material, such as iron sulfid (when H₂S is desired) is placed in the lead basket and the dilute acid in the glass jar. When the smaller bottle is placed in the jar the acid, reacting with the iron sulfid, engenders a flow of H₂S which forces the acid out of the basket if the stopcock is closed. When the stop-cock is opened, the gas escapes and allows the acid to touch the iron sulfid, again causing the formation of H₂S. Thus gas is always easily procurable without waste of material.

The generator, when in operation, is beautiful to look on. The gas is seen issuing from the stop-cock in a beautiful little stream of smoke, and the result is not unlike the effect of a miniature volcano. The smoke is caused by the heat generated in the closed jar, and this effect may be increased by introducing a small quantity of absorbant to the gas, which will cause it to be retained in the jar. A piece of lead is also valuable in this particular. Allowing the gas to pass thru a piece of lead will result in the formation of a beautiful ignite on a sheet of paper.

TESTED CHEMICAL LABORATORY STUNTS.

1. Spoons That Will Melt in Hot Water.—Fuse together in a crucible 8 parts of bismuth, 5 of lead, and 3 of tin. These metals will combine and form an alloy, of which spoons can be easily made which possess the remarkable property of melting in hot water, coffee or tea.

2. A Self-dancing Egg.—Take a thin glass tube about 3 inches long and fill it with mercury then seal both ends with good hard wax. Next have an egg boiled and then break a small piece of the shell from the smaller end and thrust the tube with the mercury in, lay it on a table and it will not cease tumbling until the egg is cool. The same can be done by taking a small balloon and blowing it up, then warm the balloon, it will stop about as long as the heat remains.

3. To Give a Piece of Charcoal a Coat of Silver.—Lay a crystal of silver nitrate upon a piece of burning charcoal; the metallic salt will catch fire and will emit sparks of various colors. The silver is reduced, and, in the end, produces upon the charcoal a very brilliant and beautiful appearance.

4. In Water But Not Wet.—Powder the surface of a large or small vessel of water with some lycopodium, which may be obtained at any drug store; you may then challenge any one to drop a coin into the water, and that he will get it without wetting your hand. The lycopodium adheres to the hand and prevents its contact with the water.

5. Artificial petrifications (turning into stone).—In a retort place a small quantity of pounded fluor-spar and sand, and pour upon it some sulfuric acid; fluorosilicic acid gas will be disengaged, holding silice in solution. The subjects you wish to petrify must be moistened with water and placed in a vessel connected with the neck of the retort, the silice will be precipitated upon them like a frost and will have a beautiful appearance. It will wear for years. Note: Do not breathe in this gas.

6. An Experiment With Sugar.—Take about 5 or 6 pieces of lump sugar and place them in a cup; next pour about 3 tea spoons full of boiling water upon them, and then add some sulfuric acid. It is truly a wonderful spectacle, and more instructive than reading, to see the sugar turn black, then boil, and now, rising out of the cup in a black color. It is now charcoal.

7. To Melt Steel.—Heat a piece of steel to redness in a fire, then hold it with a pair of pincers. In the other hand take a stick of brimstone or roll sulfur and touch the piece of steel with it. Immediately after their contact the steel will melt and drop like melted butter.

8. Explosion Without Heat.—Take a crystal or two of nitrat of copper and bruise them; then moisten them with water and roll them up in a piece of tin-foil, and in a minute the foil will begin to smoke and soon after will take fire and explode. Unless the crystals of copper are moistened, no heat will be produced.

9. To Melt Lead in Paper.—Wrap up a very smooth piece of lead in a piece of paper, then hold it over the flame of a taper; the lead will be melted without burning the paper providing there are no wrinkles in the paper and that it is in contact with the lead everywhere.

Contributed by EUGENE McGOWAN.
Electric Engraving Apparatus
(1,289,001; issued to Andrew M. Braggings]

An electric engraving apparatus employing a source of electric current for impressing characters on a metallic body to produce the engraving. It consists of an apparatus employed with graduating tools, etc., for marking metal parts of machines, etc. A further object in the invention provides an auxiliary electric current or circuit connected to the pencil, and means in the pencil for controlling the make and break of the auxiliary circuits to open and close the main circuit so as to prevent arcing when it is raised from the work. This apparatus eliminates this objectionable feature. The case contains a transformer, also a number of switches, by which the character of the current may be varied at will.

Application for Patent
(1,288,117; issued to Francesco Morano)

The chief object of this invention is a metallic microphone for high currents, which microphone is constituted by one or more metallic gripping contacts, which gripping contact is formed of two contact elements, one of them grips the other. The gripping element is firmly mounted by the diaphragm, whereas the other element is supported by such means that the pressure of the contact which is formed by both elements accurately affects it. In consequence, the electrical resistance of the contact itself may be capable of varying in rigid conformity with the vibrations of the diaphragm according to the amplitude of said vibrations.

Apparatus for Locating Sunken BodieS
(1,287,507; issued to Patrick B. Delany)

Sunken ships and bodies, by the use of this invention, may be found very readily. It is an electrically operated device, used with some form of communicating device, such as a telephone receiver, and acts upon the principle of the circuit being closed, and having normally a certain definite resistance, i.e., the inventor does not use coils conductively or otherwise for the detection. The bare electrode is lowered by means of an insulated wire through the water, and depends upon actual contact with some metallic body for its location. The circuit is formed thru a pair of sensitive head receivers, the bare electrode, the water and the electrode, and normally is of high resistance.

Recording Telephone
(1,290,021; issued to John F. Maloney)

A new form of recording telephone is more or less on the style of the dictating telephone. A device in convenient size and weight for use on office desks, etc. It is constructed so that it may be used for receiving direct dictation over the telephone, and also be used to receive telephone messages from the ordinary telephone receiver, and in this manner to record the same on a photograph record. Particular attention is attached to a new form of reed diaphragm constructed of the same width from end to end; approximately at its center is mounted a square soft iron disc held in place by clips, which on its under side has a holder for supporting the suffire point of the photograph.

Advertising Lamp and Radiometer
(1,290,749; issued to Edward J. Hunt)

The device consists of a motor operating on the principle of the radio-motor in which the moving motor elements are caused to rotate upon their axis by the action of the light. The device is primarily intended to be inserted with the enclosure of any ordinary incandescent lamp and combined with the filament support in a manner permitting the use of the usual lamp filament, so that the light issuing therefrom shall cause the rotation of the several motor vanes. The motor element consists of a series of vanes, preferably four or more, on silvered upon one side and blackened upon the other side with carbon or lamp black.

Secondary Or Storage Battery
(1,285,660; issued to Bruce Ford)

A new type and form of storage battery, its principal object being to minimize leakage between cells and still have a multiple voltage battery of sufficient strength to withstand the stresses and wear arising on such a battery. The structure may be described as a number of plates having a central portion, one face provided with a negative formation and the other face having a positive formation, with a rim projecting beyond both formations so as to fit and be pressed into soft rubber tubing, which will make it leakless. The spaces between are filled with an electrolyte, which may be any liquid, or else held in blotting paper or some other gelatinous formation.

Method of Telephonic Transmission Without Return-Wire
(1,287,180; issued to C. Bardoloni)

A new method of transmitting speech without a return wire. It is common necessary to use a separate single wire for telephonic transmission without earth return. A condition like this might exist in connection with an observation balloon, where the stringing of the separate telephonic cable would not be feasible. Under these conditions the circuit does not close by conduction, but remains as an open circuit, the return being formed by one or more metal conductors, squares, electrostatically and electromagnetically connected between each other. This invention has the object of effecting telephonic transmission by the variations of the electrostatic and electromagnetic conditions, without any metallic conductors, or the earth, connecting the circuits of the system.

Radium-Applicator
(1,288,048; issued to George Kunkle)

A radium applicator adapted for the use of radium and other radioactive salts. The applicator is properly calculated in proportion, and arranged so that the physician using it can accurately measure and administer by any of the approved methods the correct dosage at any moment by a simple adjustment of parts. This instrument manually and even irritatingly surfaces of widely various areas, as, for instance, areas of from one millimeter to thirty-two centimeters in different directions.

Compass-Gyroscopic
(1,289,813; issued to Emil Klahn)

The invention consists primarily in mounting the gyroscopic in such a manner that at all times it is unaffected by gravity, and utilizing this property of the gyroscopic to regulate the position of the controlled member, when a disturbing force is acting on the gyroscopic. Its application is mainly a non-magnetic compass, when such disturbing or directive force results from the rotation of the earth, and for movements and changes in the course of a vessel carrying the compass, and apparent rotation of the compass card or controlled member taking place and serving as a measurement of the change in course. The gyroscopic is a small apparatus, in which the gyroscope is rotantly mounted. A resilient means is connected with the frame adapted to work on the gyroscopic, when the control member or compass card is in connection with said frame.

Thermostat
(1,287,188; issued to He instrich Beck)

A new design of thermostat, which to a certain extent eliminates many of the troublesome factors of the old style apparatus. This type of thermostat is one which employs but one movable contact, the other being fixed, adjustable, and the two thermostat elements generally control the single movable contact, in response to a variation in temperature. But only one is subject to the action of radiant heat, and acts directly upon the carrier, and thereby acts directly upon the moveable contact. The heat ray may be concentrated on the thermostatic element by means of a condensing lens. The element is at a normal room temperature, and is in such a manner that the heat beam strikes the thermostatic element, and then in a manner so that this moves a crank upon the carrier, thereby closing the circuit.
“Amateur Electrical Laboratory” Contest

THIS MONTH'S $3.00 PRIZE WINNER—RAYMOND L. CASSELL

HEREWITH I present three pictures of my Electrical Laboratory. In this "Lab" you can find anything from a binding post to a six hundred thousand volt Tesla coil. I have constructed two high potential transformers and one welding transformer with output of three volts and five hundred amperes. Practically everything in this "Lab" was built by me. There are several motors, both A. C. and D. C., dynamos, about a dozen spark coils, transformers, storage batteries, small steam engine, rectifiers, Tesla coil (Oudin type), switches of all kinds, telephone instruments, condenser, volt and ammeters, et cetera. I can get a twelve to fourteen inch spark from the Oudin coil. If the spark is not drawn off, it will brush discharge to a length of ten inches, crackling and waving like a thing alive. I perform some very interesting experiments with the coil. I also have a small storage battery set with a separate switch-board for charge and discharge. I have a searchlight (arc), which will throw a beam about two miles. I operate this on a 110 volt circuit with a transformer built for the purpose. I am now building a 330 watt D. C. dynamo. I experiment with almost everything going and a lot more.—Raymond L. Cassell, Roanoke, Va.

HONORABLE MENTION (1 year's subscription to the "ELECTRICAL EXPERIMENTER")—J. H. ENGLAND

HEREWITH are photographs of my Laboratory. In one of the photographs may be seen my "Wireless Table," which contains all the different instruments used for both sending and receiving. The transmitting set consists of a 1/4 K. W. step-up transformer, condensers, spark gap, key, ammeter, et cetera. There is also a 1 inch spark coil for sending short distances. For receiving I have used successfully (before the war) a tuning coil for short distances and a home comb for long distances, in connection with a silicon detector, 2,000 ohm Brander's phones, bugging coil, variable and fixed condensers. To the left may be seen my switch-board, which is home-made. It contains a number of different switches, a buzzer, a lamp resistance, and a pilot lamp. To the left of the switch-board there are several shelves on which are different electrical books, such as "Hawkins' Electrical Guides," Houston's "Electricity in Everyday Life," and many others. There are various other instruments on this table, such as telegraph key and sounder, electric fan, Solderall torch, and an interrupter. Another photograph shows the chemical and photographic table. This table consists of a complete developing and printing set. To the left will be seen the printing box, which is home-made. The frame is an Auto Mask Printing Frame and is secured to the box by means of small hooks, so as to permit it to be removed easily. Inside there is a red and a white light. To the right there are a large number of chemicals, such as nitric acid, bromine, sodium, et cetera. This part of my "Lab" comes in handy when I need a picture of some electrical experiment. This laboratory is the result of but one year and a half of earnest work and study.—J. H. England, 509 George, Greenwood, Miss.
Science in Slang

Jazz Stokes on Wireless Dope

By EMERSON EASTERLING

"I saw a while back in a paper that Tesla and Marconi were expressing their ideas on interplanetary wireless communication. It don't look very reasonable to me that it could be done in the way that they proposed it, but I don't say that the feat is impossible," remarked Jazz Stokes the other night.

"How does a wireless wire?" asked Bender.

Heiney Hertz — Who While Monkeying Around Spark Coils and a Micrometer Spark Gap, Fell over the Hertzian Wave.

"It don't wire, that is why they call it wireless," returned Jazz.

"Well," I put in, "of course, Punk and I know all there is to know about wireless, but for Bender's sake I wish you would tell us a little about wireless."

"You are probably familiar with the African tumb-tums and the Indian signal fires," he began. "They were the original form of wireless.

A scientist by the name of Hertz, Herr Heinrich Hertz, got to monkeying around with spark coils and developing the micrometer spark gap or resonator. This apparatus worked on the principle that electro-magnetic waves radiate from a point of discharge. The twinkleing spark between the gap was due to induced current, being virtually a secondary coil of one turn. Well, this set Heiney to deducing, and he deduced the present Hertzian theory of wireless wave radiation.

"While Heinrich, never having caught up with the second syllable of his first name, died a poor man, Nick Tesla hadn't been napping either. The whole wireless dope to this bird was an unsealed book as early as 1882, when Marconi still slid down the hamster in his knickers. Thus we see Nikola two-stepning it nonchalantly to the Pat. Office, where he grabs the first REAL wireless patent along in 1900. The old boy had it all down in black on white, aerial, ground, spark gap, et al—the real, honest to goodness dope. This earned him the title of "Papa of the Wireless." But in those days there were no detectors and few experimenters to boast. So the then wiseacres sniffed at Nick's Patents, tapt their foreheads significantly and made known that this wireless stuff was all loco, bunque, and then some. The same gizmos today however sing a different tune and admit that in 1900 THEY were fast asleep and deadner than an Egyptian mummy, with heads as sold.

"Then along comes Kid Marconi and devils around with oscillators, sending waves thru buildings and other masses until he gets to work and builds a real wireless telegraphing station. By sticking his aerials up so as to clear the buildings and other masses he finds that he can send and receive for miles instead of blocks. In 1901, on the twentieth day of December, he shoots a 'can-you-get-it' across the Atlantic—and they got it. Soon all the first class vessels were equipped with radio men and added antennae to their rigging, in that they could let the world know that all was off with them by their C. Q. D. and S. O. S. yelps, instead of leaving floating spars upon the bight deep for some long to sight later.

"Marconi went on improving his apparatus and handled the financial end so that besides being a first rate experimenter and Italian gentleman of standing, he don't have to eat macaroni with a pencil.

The world wallows along, and the patent offices pile up the documents in the wireless department, when an ardent bird, Dr. Lee de Forest, waltzes on the stage of industry, to the tune of "N' EVERYTHING and shows us something. You might mistake it for an incandescent bulb, but it is as much like a light globe as a Victrola is like a centre table. We call it the Audion Amplifier, and with it in your receiving set you are able to make a squeal a scream. The wireless nuts first found that it was a scream when the ionizing sunlight failed to close the Hula-hula island and 'Frisco communication in the wee sma' hours of the morning, after the hour that the other detectors went mad on 'em.

"For Bender's sake I will give you 'Kicks' the line up on a simple wireless station. First the transmitting apparatus obtains its juice from batteries or other sources. Is that plain? Yes, well next there is a spark coil that steps the voltage up to a dangerous stage and a spark gap that lets the high tension current break down across the air space. This discharge sets up an oscillating current of high frequency. To increase the efficiency there are condensers inserted in the circuit—these store up and discharge the juice like a nigger squiring prune juice thru his teeth, only very much faster."

Taking a pen and pad from his pocket Jazz proceeded, "It is like this—see the K is the key; C, coil; e', condenser; A, aerial; G, ground; and B is for the source of juice. Then the receiving station is like this—A, aerial; D, detector, R, receiver. There is added more stuff to sensitize the layout, but they would only look like a telephone central station wiring diagram here on paper, and besides, there are more different kinds than there are ways for a young boy to go wrong.

In Guglielmo Marconi's original contraption the Signor used a coherer, where we use a detector or audion now. The coherer works by being welded by the incoming waves, the electrical resistance being less when the filings in the coherer are welded. The current is so regulated that when the wave waltzes in and unites the nickel and silver filings, the sounder that is connected in the circuit bangs down with a faint tap. The coherer is tapt by a de-coherer, jarring the nickel and silver filings loose for the next dot or dash.

"The detector rectifies the oscillating current, making it fit to vibrate the diafram on the receiver that the 'Radio-bug' has glued on here.

"The audion is an incandescent bulb with a parallel grid and plate, working on the theory that current will flow "That word is Kick and not Hick. Kick is a San Francisco slang word—it means almost anything, originating from a kick in horse and now applying to almost anything, good, bad, and indifferent."

500 K. W. DYNAMO DEVELOPS BURNT SPOTS ON COMMUTATOR.

Geo. W. B., Chicago, Ill., inquires of the "Oracle",

Q. 1. What causes commutator bars to burn, blacken and roughen up in the following manner? There are about 4 bars under a set of brushes and every set of 4 bars spaced equally between centers of field poles, all blacken. Description of machine: D. C. 500 K. W. rope drive, 8 poles, compound wound, 220 volts. Even airgap all around, commutator undercut, commutator true, field coils equal strength, no reversed coils, no overload, machine runs alone most of the time; sometimes in parallel with a 150 K. W. Brushes have a perfect gloss, practically no sparking. Four hundred segments to the commutator, all tight. Sanding commutator stops the trouble for 2 to 6 months. What causes it?

A. 1. We were particularly interested in the phenomenon you describe where the 500 K. W. D. C. dynamo, which also apparently in perfect shape and maintenance, develops burnt spots all around the commutator at points corresponding to the spacing of the brush studs.

The Editor of the Oracle, while serving as engineer in a large power house some years ago, had similar trouble, and it practically solved by any of the experts who attempted to remedy it. Also in this case, it is clearly recollected that the machine, of about the size you mention, was in very fine running condition, and every thing seemed to be in favor of its perfect operation. But still these spots developed just as you state. After some thought on the matter it would seem from later experiences that some of the following troubles might be the cause of these burnt spots appearing on the commutator:

1. From experience with several smaller machines, especially motors on elevator service, it is found that all discharge currents, which are often of very high instantaneous e.m.f. value, would be liable to cause this burning. The remedy, or rather safeguard, against such trouble from this source would be to provide a field break switch fitted with an extra contact, so that when the switch is open half-way it makes connection, so that the field can discharge through, and in some cases has been formed of a lamp bank, and if you try this, you will be surprised to see how brightly the lamps flash up whenever the field switch is opened. When the dynamo is being shut down and after the main D. C. bus-bar switch has been opened. The field magnet, of course, possesses very high self-induction, and when the field switch is opened, a very high self-induced current occurs in the field winding, tending to prevent the magnetization, and causing therefore, a very heavy current of high e.m.f. to occur in the field winding—testing to prevent the magnetization, and causing therefore, a very heavy current of high e.m.f. to occur in the field winding—testing to prevent the magnetization, and causing therefore, a very heavy current of high e.m.f. to occur in the field winding—testing to prevent the magnetization, and causing therefore, a very heavy current of high e.m.f. to occur in the field winding. Practical all dynamos above 50 K. W. capacity are equipped with proper protective field discharge resistance and field break switches of the type described.

2. It seems that insufficient brush tension would also cause this trouble, not perhaps while the machine is rotating at its normal speed and load, but due to a tendency while the brushes in such a case might have to jump when the machine was started.

3. Another possible but hardly probable source of this burning might be traced to hard commutator bars. High mica would also cause the trouble, but as you state, in your particular case the mica has been undercut.

4. Trouble is often experienced in power-station work where two or more dynamos are run in parallel, and especially when there is any weakness in the design of the equalizing circuit between the two or more machines, which may cause heavy cross currents to pass between the two machines. As you will readily conceive, such a current might be caused by a parti l unbalancing of the load between the two machines, might cause a momentary and in fact a fairly high e.m.f. transitory current to pass thru the brush and commutator system of one of the machines, and such a current would tend to have the effect of producing the burnt commutator.

5. Another trouble which would seem to point very strongly as a frequent source of this trouble, and one also that is very often overlooked entirely, is the unequal distribution of the armature current in such a large machine as this. The Editor recollects a case at one of the southern universities a few years ago, where no end of trouble was experienced in the operation of a large D. C. generator unit, due to this very reason, i.e., the unequal distribution of the current thru the armature. From a defect in design, for that, of course, is what it is, causes a number of current paths to be formed up periodically, and comparatively heavy currents will start flowing along these paths, their area being that enclosed between the axial lines of the two field poles in most instances. In the case in question, this was finally solved by the proper designing and installation of

The Opportunities In Draftsmanship

By CHAS. W. MOREY
President Chicago Technical College

During the twenty-five years in which I have had exceptional opportunities to observe the progress of technical work of every character, I have never known of such opportunities as exist today for competent draftsmen.

Very naturally the war had a great effect in producing the present conditions. Men were drafted from their drafting rooms to the trenches, leaving great gaps in our industrial organization which have not yet been filled.

And now when the war is over, we find many men not returning to their old jobs. We see business pushing harder than ever for markets. We hear of great building operations to be undertaken. We see a vast area of Europe devastated beyond description, to be rebuilt and very largely I believe with American materials and with the help of American technical experts.

When it is considered that the draftsman must be employed on every detail that goes into the manufacture of structural work of every kind, machinery, ships, roads, buildings, etc., the vast field for men in this profession must be somewhat appreciated.

The problem before thousands of ambitious young men is not whether to become draftsmen or not, but how and where to learn most quickly and thoroughly.

Formerly it was necessary to attend a resident school, which often meant giving up a position, Blacks and time as well as money. It also often meant, if a man wanted to graduate, taking studies not really bearing upon technical training. Some got their training in drafting rooms of factories, architects' offices, or other places where they started out as boys and slowly worked their way up.

It has remained, however, for correspondence instruction to give every man a chance to become an expert in any branch of draftsmanship without leaving any job he may have and as quickly as his industry will let him pass from one lesson to another.

The Chicago Technical College by its method of training has prepared, and is now preparing men, who, as a result of their education, are earning well at home and then stepping into high-paying positions.

By this method no time is wasted on unnecessary branches. The student gets exactly the training he will use in practical work and in every case he has the direct personal instruction of specialists in the branch he has selected.

Before he decides about enrolling, any man can easily find how well he stands in the art he may be to follow Draftsmanship. A test lesson is sent free to show the plan of instruction and to give the prospective student a chance to "size himself up.

We are ready to help ambitious men to get into this great profession with the least expense of time and money. We believe in the opportunities are the calls we have to furnish good draftsmen to every kind of an organization prove every day that the job is always ready for the man who can fill it. If young men throughout the country could really what a future there is in Draftsmanship, many a one would be wondering what his future is to be would come to a quick decision.

I hope that every reader of the Electrical Experimenter who is now doubtful about the calling he is to follow will write for information on one of our Drafting courses. If in doubt about which branch to take up, a letter sent to me personally will bring suggestions based on my own experience and that of our staff.

The Opportunities In Draftsmanship

Make a Bigger Income

Learn Draftsmanship

Great demand for draftsmen now. Still greater demand prospect. War over, building is to be resumed and manufacturing to expand to meet greater foreign needs—which means plenty of good positions for draftsmen. Take up this rewarding profession. The Chicago "Tech" method is the quickest, easiest way to become a draftsman in space while you hold your present position. That proved before you pay a penny. (See free lesson offer below.) Send coupon. Learn how to earn

$25 to $100 a Week or More

at interesting work with opportunities to rise to superintendent, manager, or other executive positions. Let the Chicago "Tech" engineers train you—At least get the free lesson and information.

Drawing Outfit

(No Extra Charge)

Every student of the Chicago Tech If the study course in Draftsmanship receives this drawing outfit—set of instruments in case, drawing board, T-square, triangle, scale, curve, drafting pins, pencils, etc., or a cash credit in case he already has an outfit. You use them while learning how take them right into your practical work.

NOTE: You have the personal direction of practical engineers and architects who teach the methods they use in their own work. No mumbo jumbo, no time wasted. You are prepared to start working the minute you begin the course. Send a check or a cash credit to the "Tech" for the outfit—this outfit is worth at least $10.

Come To The College or Train At Home

When you can't come to Chicago 'Tech' and don't want to take a Residential course, you can train at home in Draftsmanship. You are supplied with a complete outfit, all the instruments you need. You send in your work to the school for marking and correcting. You write in if you have any questions. You take the same course, all the same fees, as the Chicago student.

Auto and Gas Engine Course

All about automobile mechanics—its construction, operation and repair. Everything taught by mail, written work. You train at home under the Chicago "Tech" automobile experts. Splendid opportunities open now.

Learn All This in Spare Time

All about the Principles of the Automobile

All about Gasoline Engines

All about Carburetors and Fuel Systems

All about Ignition

Learn How To Fix Troubles

Complete instruction in auto repair. You send in your machine, free advice and help. The experienced Chicago "Tech" men take care of your car or machine. The coupon will get you started.

CHICAGO TECHNICAL COLLEGE

445 Chicago "Tech" Building, Chicago

Mail coupon today if you wish to learn the Chicago "Tech" way, the complete and efficient way.

Without obligation upon you, send your Catalog on subject indicated below. You will receive a free lesson in Drafting of Plan Reading. If in any line of work you are specially interested, so indicate. Mail coupon today if you wish to learn the Chicago "Tech" way.
ELECTRICAL

Preserve Your Phonograph Records!

E—Ordinary Steel Needle, new.
F—Semi-permanent Needle.
C—Sonora Needle having parallel sides, always in record groove perfectly and has a tendency to wear the record.
B—Ordinary Needlereed, using in wax paper, it can be cut to any size and record groove perfectly.
A—Fine Stainless Steel Needle.

Semi-permanent NEEDLES
Replace steel needles!
They play 50 to 100 times without wearing out
Use Sonora Needles for mellower tone, greater economy, convenience and for longer record life.

CAUTION! Beware of similarly constructed needles of inferior quality

THE ORACLE.

(Continued from page 886)

current equalizing rings placed on the back of the armature, as shown in the accompanying illustration.

Many different windings have been proposed and used successfully, but the majority of direct-current armatures are wound with either the single-parallel ring winding, or the single-series drum winding, or the single-series drum winding. The single-parallel drum winding is probably more used for other than on large multipolar machines, any unbalanced condition in the magnetic circuits is likely to cause the current to divide unequally among the several paths in the armature. For example, if the air gap on one side of the armature becomes slightly shorter than that on the opposite side, which may easily occur due to wear of the bearings, the flux in the short air gap will become unduly dense, thus causing the generation of higher e.m.f. in the armature conductors on that side than in those on the other side, and the path that develops the highest e.m.f. takes the greatest share of the current. In some cases this unbalanced condition may not be had enough to cause trouble other than some slight sparkings, but in extreme cases, the line of the path on one side of the armature may become so excessive as to reverse the current in some of the other paths, making part of the armature act as a generator and part of it as a motor at the same time.

This condition is usually accompanied by some vibration of the whole machine, due to excessive mechanical strains, with more or less violent sparking or flashing at the brushes, and the machine is said to be "bucking," in which the effect of the unbalanced condition may be eliminated by providing the armature with equalizer rings as shown.

By means of equally spaced leads these rings connect points of equal potential in the winding and allow an equalization of current between the various paths in the armature.

Sometimes erratic line disturbances, motor flare-backs, defective motor control apparatus, will cause the effect you describe.

We would recommend that you look up some of the books by D. C. machines and see what they say about the effects of armature reactions, bucking is somewhat more liable to occur in motors than in generators, for in the armature, the effect of the unbalanced condition may be eliminated by providing the armature with equalizer rings as shown. By means of equally spaced leads these rings connect points of equal potential in the winding and allow an equalization of current between the various paths in the armature.

CAUTION! Beware of similarly constructed needles of inferior quality

HOMOPOLAR DYNAMO.

(990) O. S. M., U. S. N. R. F., writes:
Q. 1. Giving a sketch of a commutatorless dynamo, in your February, 1898. Also you would do well to refer to Professor Thompson's complete treatise, "Dynamo Electric Machinery," and a most thorough cover on the subject in the design and calculation of the electrical as well as the magnetic circuits of the "homopolar" dynamo, is given in Prof. Alfred E. Wiener's excellent book, entitled "Continuous Current Dynamo Electric Machinery Design." These books are available through Book Department.

The outline of the action of the machine you show is in accordance with the opinion of this machine given by Prof. Silvanus Thompson, in which he says in part:

"There is a class of dynamo-electric machine, differing entirely from any of the commutating types, in which the coil or other movable conductor slides around one pole of the magnet and cuts the magnetic lines in a continuous manner without alternations in the direction of the induced currents. Such machines, sometimes called "homopolar" or "uni-polar," have a very low resistance, and the Faraday's disk machine belonged to this class.

The stream that has been supplying the ancient city of Damascus with water for forty centuries has been harnessed to provide electricity to light the city and operate a water-pumping plant.

According to an Italian scientist's figures, a square mile of the earth's surface in six hours of sunshine receives heat equivalent to the combustion of more than 2,000 tons of coal.

BAILLIS COST FOR ALTERNATING CURRENT ARC-LAMP.

(991) Henry Tustin, Ocean Grove, N. J., writes:
Q. 1. I am having trouble in operating an experimental arc-lamp on 110 volts. What can you suggest?
A. 1. Regarding the operation of arc lamp at 110 volts house lighting current, you do not state what kind of current you have, whether alternating or direct. For one thing, this factor will determine whether your experiment will be a success or not, for the reason that if you are fortunate enough to be alternating current, then you will find invariably that it will not operate well using a simple resistance coil or rheostat in series with it.

For alternating current operation the proper ballast consists of an adjustable impedance or choke made up of an iron core or laminated sheet iron core on which various lengths of magnet wire are wound. Where an ordinary C. P. arc, such as used in ordinary street lighting, etc., is employed and taking about 5 amperes on 110 volts, the impedance coil may be composed of an iron core about 4" in diameter, wound about six layers of No. 14 C. C. magnet wire, taking off taps from the third, fourth, fifth and six layers.

We very strongly surmise from the symptoms you give in your letter concerning
You can be a Graduate

ELECTRICAL ENGINEER

Our method of teaching saves you time and money in becoming a graduate, practical, Electrical Engineer—at Big Pay.

There is a large and constantly increasing demand for Graduate Electrical Engineers. Our Diploma is accepted as evidence of a competent, trained electrician. Hundreds of our Graduates are now big, successful Electrical Engineers. They will tell you what we have done for them. We can do the same for you—in your spare time at home. Read how these results are accomplished:

Your object in taking a correspondence course is to Increase your Earning Power. To learn exactly what you need and not waste your time and efforts on superfluous matter, is the shortest means to that end. The Joseph G. Branch School of Engineering specializes in equipping you with the practical and usable knowledge that enables you to qualify as an Electrical Engineer in the shortest time, yet our course is practical and complete. This we definitely guarantee.

You Get Intensive, Selected, Personal Instruction

Our courses are simple, practical and easily understood. Everything is made clear. You do not become involved in difficult technical matter of no practical value, and which is so discouraging to the student, but you go straight into the principles of the subject and the application of these principles. Every one of our students gets personal instruction, so that his progress is steady and sure. You can’t fail with this course if you will simply follow our very clear directions. One of our students says: “Your course is strong for the Engineer. It gives him the vital working knowledge of the subject which makes him a competent Electrical Engineer in a very short time and at a very moderate cost.” Many Electrical Engineers earn $2,500 to $7,500 a Year

The course in Electrical Engineering covers the installation and operation of all kinds of modern electrical machinery and appliances, including power plant work, viz.: Practical Electricity, Alternating Currents, the Electric Motor, Practical Mathematics and Electrical Wiring. Under Practical Electricity both direct and alternating currents, high potential and high frequency currents are covered.

You get everything that will make you a proficient, practical Electrical Engineer—without the loss of time spent on endless theory and difficult technical work of other methods. This has been made possible by the thirty years of practical experience of Mr. J. G. Branch, B.S., M.E., in the engineering field. This is now presented to you in compact, usable and easily learnable form. There is no course which will put you on a big salary basis in so short a time.

THese BOOKS FREE!

With the Electrical Engineering course you get, FREE, these splendid text books—all Standard Works. These books alone are worth more than the price of the course. Each book by a recognized authority:

Practical Electricity
Alternating Currents
Electric Wiring
The Electric Motor
Simplified Practical Mathematics

You need this Electrical Library. Here is your chance to get it free.

Due to Mr. Branch’s long experience in and close contact with the engineering field the courses embrace such questions as are usually asked by the various Boards of Examining Engineers throughout the country. Our graduates will testify to the ease with which they were able to pass these examinations, and the cooperation received from us in helping them get positions.

A Diploma from the Branch School of Engineering is a sure step to a better position and a larger salary. You can soon have your Diploma—without interfering with your present work.

SPECIAL OFFER

The price of the course is extremely low and just now we are making a Special Limited Offer to those who reply to this advertisement. This remarkable offer reduces the cost of the complete course to a very low figure. You will be astonished to learn how little this tremendously valuable training will cost you. Mail coupon at once for full particulars and Special Terms. Jos. G. Branch School of Engineering, Dept. 14, 542 Dearborn Street, Chicago.

ELECTRICAL IDES complimented elements; the elastic various his "gob" organic appended a does committee in inches, conversation, naval Action, very much. For instance, we find the term "all-client" among the words very significantly "—consists of a metallic tube made to slide over insulating tube for metallic lining." This definition does not mean very much to those who have not a radio trade definition, while as a matter of fact most of the regular textbooks on wireless telegraphy describe this type of radio work in terms as definite electrical capacity of one bill-farad. This little work for a hand-book on the employment of wireless terms which may prove of considerable use to radio students and others interested generally in this line of work.

This work is something out of the ordinary and places in the hands of chemistry students and chemists in great need. It is a collection of tables and formulas worked out, which would require many volumes on chemistry and physics in order to determine these quantities. Their presence makes the giving of the complete equations for various organic compounds; physical constants of the elements; physical data, organic compounds; and analysis procedure; flame and heat testing; various solutions of ions; and a large number of tables giving glycerin factors and their logarithms; a very complete bibliography is appended at the close of the book, giving a valuable titled list of several hundred works in chemistry and physics. The volume is well indexed.

This work proved of great value during the war and is one of the most complete books on the subject of military and naval organizations throughout the world. It is the only complete gazetteer of rank in the various organizations of the armed forces of the world, but the customs of the service as well, such as etiquette of enlisted men, officers, etc. The book was composed by the Secretary of the Navy, the treatment starts with the organization of the army bureau and corps, the composition of the army and its various departments, how the staff is composed, and the divisions into the various arms of the service, such as cavalry, field artillery, coast artillery, infantry, and engineers. The book describes all the various coast artillery districts throughout the United States, their ranks here and there, as well as the duties of the officers holding these ranks, armament and customs inductively and customarily; a great many questions in conversation, when and when not to address a lieutenant by his title; how to address a colonel, etc.

The succeeding chapters take up the composition of the navy and the rank in the naval force ashore, including an explanation at length in the book 31, of the duties of the Bureau of Steam Engineering, and how it comes about that the personnel of the new war fleet is to be formed as well as what do with the installation of Radio Equipment on ships of the navy and on shore—a nice little book which is a reproduction of "Oracle Department," and of the editors person by person, every time we see a "Radio-log." We then follow interesting chapters on naval etched book, indicating what is the position of the officer in the peacetime fleet, the way he stands, and so forth. It is prescribed in the rules and regulations on naval etched book, that it is unbecoming an officer in uniform to carry a package of any kind. But at the close of the hum-drum of red tape, which tells you how you shall place your feet, and which you shall take off your hat, also when you can use your hands, etc., there comes that mighty interesting read to poor land-lubbers come to the sea. It is a book that everyone who is interested in the work in the navy must have. It tells you why it is customary for a committee of the navy to make the rules and regulations that—"is customary for the Secretary of the Navy to issue maxims for New Year’s Day all on ships in the same port," and further—when in Washington, it is customary to call on the Secretary of the Navy to issue maxims for New Year’s Day and you shall appear full dress uniform and have it accordingly leave your umbrellas at home. This is the work for officers, and it is good. We have been going through it a few times, and it is interesting, and written in a very interesting style in which he has compiled the work.

**ELEMENTARY NAVAL ORNAMENT AND GUNNERY**, by Lieut. H. C. Ramsay. Limp leather cover, size 7 1/2 x 7 1/4 inches, published by Charles Scribner’s Sons, New York, 1918, Price $3.00 net.

One of the most valuable works published during the war as a read by the students in the Naval Gunnery Schools and also as a good book for any man interested in the military and naval armaments. It has been prepared in a simple, easy and direct manner so that all classes of readers may gain a firm foundation in the essentials of the fundamentals and general principles of the art of modern naval gunnery.

The material has been gathered from lectures delivered at the Ensign School at Harvard University, and a number of instructors who have been incorporated in the work with full answers.

A few of the many important chapters follow:—Naval Guns, Manufacture of Naval Guns, Gun Mounts, Breech and Firing Mechanisms, Electrical Firing Mechanisms, Torrets, Gunpowder, Projectiles, Magazines, Inspection and Showers, How the Battery in Action, Care of Turrets, Automatic Machine Rifles, Battleship, The Gunnery Of a Destroyer, Bunkers, etc.

The chapter on Infantry has been included in order that those new to the service may understand some of the requirements as practiced in this branch of the service.

There is no doubt but that this book will fill a distinct want in the work. We are studying this subject, besides giving to the layman a real glimpse of the part Gunnery plays in every battle engagement whether on land or sea. Lieut. Ramsay is to be congratulated upon the work he has done which he has covered in the book. The reader is particularly impressed with the clearness just how the breech mechanisms of the great naval cannon work as well as the small breech mechanisms which have been described, etc. Every kind of projectile is fully explained with sections and cutaway drawings in place, computed, calculating the range from a moving war-vessel with the complications made by the wind temperature of the air, wind, order charge, etc. Most a interesting, authentic and valuable work.
Free Proof that I Can Raise Your Pay

No matter how much you are earning now, I can show you how to increase it. I have even taken failures and shown them how to make $100—$200, and in once case as high as $2,000 weekly. I am willing to prove this entirely at my risk and expense.

I T was a simple thing that jumped me up from poverty to riches I've said, I'm no genius. But I had the good fortune to know a genius. One day this man told me a "secret." It had to do with getting ahead and growing rich. He had used it himself with remarkable results. He said that every wealthy man knew this "secret,"—that is why he was rich.

I used the "secret." It surely had a good test. At that time I was flat broke. Worse than that, for I was several thousand dollars in the hole. I had about given up hope when I put the "secret" to work.

At first I couldn't believe my sudden change in fortune. Money actually flowed in on me. I was thrilled with a new sense of power. Things I couldn't do before became as easy for me to do as opening a door. My business boomed and continued to leap ahead at a rate that startled me. Prosperity became my partner. Since that day I've never known what it is to want for money, friendship, happiness or any of the enormous benefits that the "secret" surely made me rich in every sense of the word.

MY sudden rise to riches naturally surprised others. One by one people came to me and asked me how I did it. I told them and it worked for them as well as it did for me.

Some of the things this "secret" has done for people are astounding. I would hardly believe them if I hadn't seen them with my own eyes. Adding ten, twenty, thirty or forty a week in a man's income is a mere nothing. That's merely playing at it.

In one case I took a rank failure and in a few weeks had him earning as high as $4,000 a week.

Listen to this: A young man in the East had an article for which there was a great worldwide demand. For twelve years he had put out his "pentered round" with it, but barely eking out a living. He then bought a patent which was worth $200,000. He was building a $25,000 home and paying cash for it. He has three automobiles. His children go to private schools. He goes hunting, fishing, traveling wherever the mood strikes him. His income is over a thousand dollars a week.

In a little town in New York lives a man who two years ago was quitied by all who knew him. From the time he was 14 he had worked and slaved—and at sixty he was looked upon as a failure. Without in- debt to his charitable friends, with an ideal good to support, the outlook was pitch black.

Then he learned the "secret." In two weeks he was in business for himself. In three months his plant was working night and day to fill orders. During 1916 the profits were over $250,000. During 1917 the profits ran close to $400,000. And this giant 64-year-old young man is enjoying the pleasures and comforts he had little dreamed would ever be his.

I COULDN'T tell you thousands of similar instances. But there's no need to do this, as I'm willing to tell you the "secret" itself. Then you can put it to work and see what it will do for you.

I don't claim I can make you rich over night. Maybe I can—maybe I can't. Sometimes I have failed. But in my experience everyone has a friend that can help 90 out of every 100 people if they will let me. I've found a friend of it all the people using only about one-tenth of that wonderful brain power. That's why you haven't won greater success.

Throw the unused ninth-tenths of your brain into action and you'll be amazed at the almost instantaneous results.

Will is the motive power of the brain. Without a highly trained, intelligent will, a man has about as much chance of attaining success in life as a railway engine has of crossing the continent without steam. The biggest ideas have no failure without willpower to put them over. Yet the will, also heretofore entirely neglected, can be trained into powerful force the brain or memory and by the very same method—intelligent exercise and use.

If you held your arm in a sling for two years, it would become powerless to lift a feather for lack of use. The same is true of the Will—it becomes useless from lack of practice. Because we don't use our wills—because we continually bow to circumstances—we become unable to assert ourselves. What our wills need is practice.

Develop your will-power and money will flow in on you. Rich opportunities will open up for you. Driving energy you never dreamed you had will manifest itself. You will thrive with a new power—a power that nothing can resist. You'll have an influence over people that you never thought possible. Success—in whatever form you want it—is your own creation. The laws are the same for all, and all who fail are those who don't know or don't use these rules. And if you'll learn them, you'll get your share of the money to come.

How You Can Prove This at My Expense

I KNOW you'll think that I've claimed a lot. Perhaps you think there must be a catch somewhere. But here is my offer. You can easily make thousands—you can't lose a penny.

Send no money—no, not a cent. Merely clip the coupon and mail it to me. By return mail you'll receive—not a pamphlet, but the whole "SECREt" told in this wonderful book, "POWER OF WILL."

Keep it five days. Look it over in your home. Apply some of its simple teachings. If it doesn't show you how you can increase your income many times over—just as it has for thousands of others—mail the book back. You will be out nothing.

But if you do feel that "POWER OF WILL" will do for you what it has done for over a quarter of a million others—if you feel as they do that it's the greatest book to the Bible—send me only three dollars and you will be the square.

If you pass this offer up your chance to turn that small profit on a three-dollar sale. But you—you may never be able to realize what a difference between what you're making now and an income several times as big as you. Have you seen a lot—a whole lot—more to lose than I? Mail the coupon or write a letter now—you may never read this offer again.

PHELTON PUBLISHING COMPANY
301 Wilcox BLOCK—MERIDIAN, CONN.

The Moon’s Rotation

(Continued from page 806)

festy absurd and of no bearing on the question under consideration.

In all the communications I have received, the different in the mode of presentation, the successive changes of position in space are mistaken for axial rotation. So, for instance, a positionary argument is found in the observation that the moon exposes all sides to other planets! It revolves, to be sure, but none of the evidences is a proof on its axis. Even the well-known experiment with the Foucault pendulum, albeit exhibiting similar results on the globe, would merely demonstrate a motion of the satellite about some axis. The view I have advanced is NOT BASED ON A THEORY. It is MUST BE POSEST OF MOMENTUM. If there be, there is no axial rotation, all appearances to the contrary notwithstanding.

A few simple reflections based on well established mechanical principles will make this clear. Consider first the case of two equal weights a and b, in Fig. I, whirled about the centres of gyration as shown. Assuming the latter to break at a both weights will fly off on tangents to their circles of gyration, and, being annihilated with different velocities, they will rotate around their common center of gravity o. If the weights are whirled n times per second then the outer and the inner one will be, respectively, \[ V = 2(R + r)r \] and \[ l' = \frac{2\pi}{n}r, \] and the difference \[ l - l' = 4\pi r n, \] will be the length of the path of the outer weight. Inasmuch, however, as there will be equalization of the speeds until the mean value is attained, we shall have

\[ \frac{2\pi n}{n} = 2\pi n, N \] being the number of revolutions per second of the weights around their center of gravity. Evidently then, the weights continue to rotate at the original rate and in the same direction. I know this to be a fact from equal experiments. It also follows that a, as shown in the figure, will behave in a similar manner for the two half-spherical masses can lie in their centers of gravity and \( m \) and \( m \), respectively, which will be at a distance from o equal to \( \frac{4}{3}r \).

This being understood, imagine a number of balls \( M \) carried by as many spokes \( S \) radiating from a hub \( H \), as illustrated in Fig. 2, and be rotated \( n \) times per second around center \( O \) frictionless bearings. A certain amount of work will be required to bring his structure to this speed, and it will be found that it equals exactly half the product of the masses with the square of the tangential velocity. Now, if the moon rotates in reality on its axis this must also hold good for \( E \) of the balls as it performs the same kind of movement. Therefore, in impinging at a given velocity, energy must have been used up in the axial rotation of the balls. Let \( M \) be the mass of one of these and \( R \) the radius of gyration, then the rotational energy will be

\[ E = \frac{1}{2}M(2\pi R)^2. \]

Since for one complete turn of the wheel every ball makes one revolution according to the prevailing theory, the energy of axial rotation of each ball will be \( E = \frac{1}{2}M(2\pi R)^2, \) r, being the radius of gyration about the axis of rotation for 0.625 r. We can use as large balls as we like, and so make \( E \) a considerable percentage of \( E \) and yet, it is positively established that even if the rotating balls contain only the energy \( E \), no power whatever being consumed in the supposed axial rotation, which is, consequently, wholly illusionary. Something even more interesting may, however, be stated. As I have shown before, a ball flying off will rotate at the rate of the wheel and in the same direction. But this whirling motion, unlike that of a projectile, neither adds to, nor detracts from, the energy of the translatory movement which is exactly equal to the work consumed in giving to the mass the observed velocity.

From the foregoing it will be seen that in one sense the moon is corrected, but once it gets off on the wrong path, the momentum of the earth is not enough to make it be bisected by a plane tangential to the orbit, the masses of the two halves are inversely as the distances of their centers of gravity from the earth’s center and, therefore, if the latter were to disappear suddenly, no axial rotation, as in the case of a weight thrown off, would ensue.

WHAT IS MAN?

A man weighing 150 pounds will contain approximately 3.500 cubic feet of gas,—oxygen, hydrogen and nitrogen in his constitution which at ordinary pressure per cubic foot of cubic feet would be worth $2.80 for illuminating purposes. He also contains all the necessary fats to make a 15-pound candle, and thus, together with his 3,500 cubic feet of gases, he possesses considerable illuminating possibilities. His system contains 22 pounds and ten ounces of carbon, or enough to make 780 dozen, or 9,300 lead pencils. There are about fifty grains of sugar in his blood and the rest of the body would supply enough of this metal to make one spike large enough to hold his weight. A healthy man contains 54 ounces of phosphorus which his deadly poison would make 500,000 matches, or enough poison to kill five hundred persons. This, with two ounces of lime, make the stiff bones and brains. So, it might be decided that the man contains about 60 lumps of sugar of the ordinary cubical dimensions, and to make the seasoning complete, there are 20 of a portion of salt. If a man were distilled into water, he would make about 38 quarts, or more than half his entire weight. He also contains a great deal of starch, chlorid of potash, magnesium, sulfur, and hydrochloric acid in his wonderful human system.

Break the shells of 1,000 eggs into a huge pan or basin, and you have the contents to make a man from his toe-nails to the top of his head. This is the scientific answer to the question, "What is Man?"
What Would Their Advice Be Worth to You?

Suppose you have a knack for things electrical—that you realize what a wonderful opportunity for earnings and advancement the field of Electricity offers. What, then, would it be worth to you to have Edison and Steinmetz, the two foremost figures in the electrical world, tell you of a thorough, practical plan by which you can acquire, right at home, the training you need for success?

Well, here is their advice, based on years of familiarity with the instruction given by the International Correspondence Schools and on personal knowledge of I. C. S. trained men in their employ:

"I know of the success attained by men who have taken your Courses," says Edison. "It is a practical and economical way to acquire a knowledge of the profession," says Dr. Steinmetz. Read their full statements above.

For 27 years the I. C. S. have been training men at home in their spare time for success in Electricity and 280 other subjects. It is training over 100,000 men and women right now. It is ready and anxious to prepare you for advancement in Electrical Engineering or any special branch of it—or in any other line that appeals to you.

Pick the position you want in the work you like best, then put it up to us to prove how we can help you. Here is all we ask—without cost, without obligation, mark and mail this coupon.

HOW BOY SCOUTS CAN GAIN "WIRELESS MERIT" BADGE.

The committee on badges, awards and
scout requirements of national headquar-
ters has just established a "wireless merit
badge" which will become quite popular
as soon as there is an opportunity
for scouts to perfect themselves in the
discipline. The requirements are as fol-
lores:

- Be able to receive and send correctly not less than 10 words a minute.
- Know the correct form for sending a message.
- Be able to tell in own words the principal
laws regarding radio communication.
- Know at least one radio gram abbrevia-
tions (Q signals).
- Be able to name two types of detectors
and explain how they work.
- Name five minerals used in detectors
in the order of their sensitiveness.
- Draw a diagram of a simple transmitting
set, showing how the following instruments
are connected: microphone (dynamo
or storage battery), transformer, condenser,
spark gap, helix, key, and explain their
function.
- Draw a simple diagram showing how to
connect the following instruments: Tuning
coil or loose coupler, condensers, test or
variable, detector and ground. Tell the
use of the above apparatus.
- Draw a diagram of three different types
of aerials and tell their advantages or faults.
- Know how to properly ground a radio
set and know what precautions to take
during a thunderstorm.
- Demonstrate how to rescue a person
in contact with a live wire, and have a know-
ledge of the methods of administration of
a person insensible from shock.

Write a brief essay on the development
of wireless telegraphy.

ELECTRIC DRIVE FOR U. S. WAR-
SHIPS.

America’s capital fighting ships of the
future will be superior to those of other
nations because of their electrically
driven machinery, Capt. Robert D. Dalles,
told the House Naval Committee recently in
disclosing remarkable results attained by
the new dreadnought New Mexico, equip-
ted with the electric drive which is to be a
feature of all the big ships authorized since
1916.

The New Mexico’s turbo-electric ma-
machine was designed to develop 26,500
horse-power at full speed and to give the
ship a speed of twenty-one knots.

"It actually developed more than
31,000 horse-power," Mr. Daniels said, "and
maintained for four hours a speed of twenty-
one and one-quarter knots, and this when
the ship was loaded to nearly 20,000 tons
greater than its design called for.

The secretary said fuel economy at cruis-
ing speed had been one of the things sought
in substituting electric drive for the ordi-
nary turbine equipment.

Practical Chemical Experiments

(Continued from page 880)

TO TEST FOR COAL TAR COLOR-
ing. Experiment No. 3. See Fig. 3.

To test for coal tar color in butter,
a small sample is mixed on a porcelain plate
with Fuller's earth, and if coal tars are
present, there will be littleعال, while if
absent the color will be only light yellow or
brown.

Experiment No. 4.

Put little butter in a test-tube, and
a little oleomargarine into another. To each
add one inch or so of alcohol potash solu-
tion, and warm each in the steam of the
water bath until the one from the
other by smell. Add a little sulfuric acid
(dilute) to each and smell again. Notice
that "oleo" test tube will only smell of
alcohol, but the other will smell, besides,
of butyric ether.

Radium Substitute.

We are all quite familiar with the uses
of radium in medicine and as an ingredient
in luminous paint, both of which have been
brought to the general public’s attention
within the past few years.

Luminous paint in particular offers a field
whereby a substitute for Radium may be
judiciously utilized. This is not in any
important rôle in the war which has just
terminated, having been used more par-
cularly on the diaphragms of instruments used
on airplanes, so that they could be read at
night. It has also been used for electric
push buttons, door numbers, etc. The paint
is permanently luminous in the dark and
contains from 0.1 to 0.25 milligrams radium
element to one gram of zinc sulfid. A
luminous watch face usually contains from
ten to twenty cents worth of radium on it.

An excellent substitute for radium
for certain purposes is Meso-thorium. This
is a radio-active Cesium and Monazite,
and other thorium minerals. When
first extracted it is not satisfactory for
luminous paint, and consequently must be
"ripened" for several months, or even a
year before it can be used. During this
time the alpha radiation, which is required
for luminous paint, becomes sufficiently
strong. On the other hand the beta and
gamma radiation of Meso-thorium grows
and it can be put to practical purposes within a few days after prepara-
tion.

Radium, we are told, has a long life, half
of it decaying in approximately 1,800 years.
Meso-thorium on the other hand possesses
a short life, 5 or 6 years being its useful
life for luminous purposes. For luminous
paint to be used on objects which themselves
have a short life, it is an excellent substi-
tute for radium and will conserve the ele-
ment radium for medicinal purposes only.

Static Electricity and Gasoline.

Static electricity, superinduced by the
process of gasoline at a chamois skin dur-
ning the filtration process, was declared to
be full of great danger. When this idea
became prevalent, a well known automobile
concern undertook a series of rigid experi-
ments to learn what prospects there were
of real danger. Their investigations re-
sulted in their finding that the static elec-
tric charge cannot be developed with the temperature
above freezing (32 deg. F.), while at zero
(0 deg. F.) the conditions for producing
the spark are most favorable.

Two Trade Secrets.

There are two trade secrets at least that
the workmen have at a chamois skin dur-
ing the work, but which it is well worth the
while of inventors to study. One is the Chinese
method of making the bright reddish color
known as Vermilion, or Chinese red; and the other
is a Turkish secret—the inlaying of
the hardest steel with gold or silver. Among
the Chinese there are very few of the
trade who are guarded well. Apprentices, before
they are taken for either trade, are compelled
to swear an ironclad oath to reveal nothing
of the processes in the workshops; but
they also belong to families of high standing,
and must pay a large sum of money as a guaran-
(Continued on page 911)
Learn Electricity

In the Great Shops of COYNE IN 3 1/2 MONTHS

Thousands of Electrical experts are needed to help rebuild the world. Come to Chicago to the great shops of Coyne and let us train you quickly by our sure, practical way, backed by twenty years of success. Hundreds of our graduates have become experts in less than four months. You can do the same. Note is your big opportunity. Come—no previous education necessary.

Earn $125 to $300 a Month
In the Electrical business. Come here where you will be trained in these great $100,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

Become an Expert in 3 1/2 Months
No need of taking from 1 to 4 years to become an expert, we have proved this in thousands of cases. The Coyne method of practical training eliminates all books, useless theory and other non-essentials and trains you in just what you need to know to become an expert.

Earn Your Way
Don't tell yourself you haven't got the money to come to Coyne. If you have ambition and the nerve of a real man, that's all you need. Dozens of our students every year work in their spare time and earn their living expenses. Dozens of others work in the day time, earn all their expense and attend our evening school. Our employment department will help you without charge.

BENNETT W. COOKE, Director
COYNE TRADE AND ENGINEERING SCHOOLS
Dept. 24 39-51 E. Illinois Street, Chicago, III.

Day or Evening Courses
Don't worry about the money. Anyone with ambition can learn here. Our tuition is low with small easy payments if desired. All tools and equipment is furnished free. Our students live in comfortable homes in the best section in Chicago—on the lake—just a few minutes' walk from our school.

Electricity, Drafting
Motion Picture Operating
Plumbing
We teach all these trades and professions quickly and in such a thorough, practical way that when finished you are ready to step right into a position of responsibility and big pay.

Send Today for Big Free Book
Write today, now, for the book. It tells what Coyne graduates have done. What you can do. Fill in the coupon, check the trade you are most interested in or send a postal card, do it now.

Learn Drafting
The country is crying for skilled draftsmen in all lines. Thousands of positions open with princely salaries. We have been able to place every graduate in a good position. One firm asked for all our men. Now is the time to get into this big field. Experts train you under practical working conditions, no books and theory go here. Check drafting on the coupon below and mail it at once for full particulars.

COYNE TRADE AND ENGINEERING SCHOOLS
Bennett W. Cooke, Director
Dept. 24, 39-51 E. Illinois St. Chicago, III.

ELECTRICAL EXPERIMENTER

April, 1919

INTRODUCING
Mr. R. W. DeMott

For eight months past Mr. R. W. DeMott has been advertising manager of your magazine. You have noticed the rapid growth of "E. E." during that time. One big reason for this astounding growth and betterment of your magazine is due directly to Mr. DeMott and his "ads."

If you have the welfare of your magazine at heart, read Mr. DeMott's message. It means money to you.
The Publishers.

Advertising Talks

You, as a reader of the ELECTRICAL EXPERIMENTER, grow through the influence you derive from reading articles of permanent interest in every department of the magazine. There are some very strong reasons why you should be doubly interested in the advertising pages of the ELECTRICAL EXPERIMENTER.

The publishers are constantly striving and planning to improve the quality of the magazine offered you each month. But it is your magazine and it is up to you as to how big it shall grow. There are a great many things that you ought to know about advertising and how this powerful force affects you personally. Progressive and responsible firms all over the country announce what they have to offer you through the advertising pages of the ELECTRICAL EXPERIMENTER. Not only will they help your magazine by showing an interest in its advertisers, but you will benefit yourself to an even greater degree. I will take up these points one by one each month, and hope that every reader will follow this column and offer any suggestions or ask any questions that may come to his mind regarding advertising and its relation to a big magazine.

If you have any suggestions to make regarding the advertisements that appear, if there is any information you would like to see advertised in general, write me personally and your questions will be taken up in due course through this column. For the time being I will tell you about "E. E." advertising and its relation to you. Each month I will give you one reason more why the advertisements should be of vital interest to everyone of us.

You have watched the EXPERIMENTER grow from a single-page magazine to its present size. You have watched the class of articles improve, its staff of authors, who contribute each month get bigger and better, finally resulting in the wonderful announcement made in our January issue that the magazine is acquired by you for the services of the world's greatest inventor, Nikola Tesla, to give you exclusive feature articles in every issue for the next two years at least.

One of the principal factors in this rapid growth has been advertising. Next month I will show you how, by reading and answering the advertisements, you will help to still further the cause of increasing the size of the EXPERIMENTER.
WHAT IS A “KILOWATT” AND “KILOWATT-HOUR”.
By Frank Szabo.

THERE seems to be quite a wrong conception of the terms kilowatt and kilowatt-hour. Quite frequently one hears expressions such as “10 kilowatts per hour”, but such an expression does not mean anything.

What is a kilowatt? Kilowatt is a term for power or rate of work. According to Kent and other authorities, one kilowatt is the energy consumption of one hour of 3.52 lbs. of water per hour from and at 212 deg. F., or 3.415 heat-units per hour. In this definition, per hour is a necessary part of it, without which the definition is incomplete. If it takes approximately 3 lbs. of burning coal to evaporate 3.52 lbs. of water from and at 212 deg. F., then one kilowatt represents the consumption of 3 lbs. of coal per hour, and not simply the consumption of 3 lbs. of coal. If we extend the evaporation of 3.52 lbs. of water from and at 212 deg. F. by a consumption of 3 lbs. of coal uniformly over a period of two hours, we do not have the equivalent of one kilowatt, but one-half, or ½ kilowatt, because during one hour only one-half of 3.52 lbs. = 1.76 lbs. of water have been evaporated with a consumption of one-half of 3 lbs. = 1.5 lbs. of coal. Also, if we did the above performance in 30 minutes, or one-half hour, we would not have the equivalent of one kilowatt-hour, but one-half, or ½ kilowatt-hour, because at the same rate we would, during one hour, evaporate 2 x 3.52 lbs. = 7.04 lbs. of water with a consumption of 7.04 lbs. of coal. Hence, one kilowatt represents the consumption of 3 lbs. of coal per hour.

Of course the quantity of 3 lbs. of coal in the above example is not fixed, but may slightly more or less than 3 lbs. per hour for one kilowatt, depending on the heat value of the coal and the efficiency of the steam and current generating units, but 3 lbs. is a fair average figure.

What is a kilowatt-hour? According to Kent, it is the evaporation of 3 lbs. of water from and at 212 deg. F., or 3.415 heat-units. In this definition, per hour is left out because no matter how fast or how slow the water evaporates, the actual work done in evaporating 3.52 lbs. of water from and at 212 deg. F. is equivalent to one kilowatt-hour.

In actual practice, one kilowatt-hour is the equivalent of one kilowatt for a period of one hour. The rate of ½ kilowatt for a period of 2 hours is the equivalent to one kilowatt-hour. Hence:

\[ \text{Kilowatt-hours} = \frac{\text{No. of hours}}{2} \times \text{kilowatt-hours} \]

The instruction work is laid out and given in a way easily understood. It is not a cut and dried book plan, but the lessons are prepared especially for the purpose for which they are used and additional instruction is given to the individual student, with a view of meeting his particular needs. I have the information to give and I believe the ability to impart it to others, a fact which is in a way proven by other institutions which have made use of my services in the design and perfecting of instruction courses. To understand this work, IT IS UP TO YOU TO SHOW I am correct in this view of the matter. It is only as you work, and work correctly, that you will make the most of the instruction, and hence, you will get the most out of this book.

The Purpose of the Course of Study
I have been designing courses in electrical instruction and teaching electricity, of and on during the past 17 years, and during that time I have had an unusual opportunity to make a special study of the teaching business, from the standpoint of a practical man. This course of my own is designed with a view of reaching those who do not have a lot of time and money to devote to study work, and to give them as thorough a knowledge as possible of electricity, in the shortest possible time. The instruction is given like you were working the various jobs and I was the boss telling you what to do and how to do it, and giving the explanation necessary for the understanding of the theory covered by the subject under discussion. There are many conditions which seldom occur in the everyday run of electrical experience, and these conditions I lay particular stress on. This part of the instruction makes the course particularly attractive and valuable to those already engaged in active electrical work.

It Is Up To You

Practical Men: Take My Course and Recommend it to Others
Sixty percent of my students are actively engaged in electrical work and find the instruction I give well suited to their needs. Several of these men have had their fellow workers take the course also and they are taking the instruction together, making a class-room proposition of it and the results are in every way satisfactory to all concerned. One of these classes was started by a Chief Experimenter, one of my students in Glen White, W. Va., who now has practically all the men under him taking my course. I believe the fact that these men who understand electrical work approve of my course to this extent is one of the strongest endorsements I could get.

FIFTY FIFTY

I work absolutely on a 50-50 basis with my students. You pay me the comparatively low price I ask, and I give you the instruction and other help as is stated in my catalog. No student is permitted to pay cash for his entire course on starting, the course being paid for in small monthly payments as you go along. Students have the privilege of discontinuing the work if they should find that it was not just what they were after, and their payments stop at the same time. This is my way of doing business and I would not want your money when I was not giving you the instruction.

Apparatus, Instruments, Material, Etc.
Certain electrical apparatus, instruments, material, drills, sketching implements, etc., as detailed in the catalog, are required to the course and are a part of the regular instruction for which there is no extra charge as it is covered by the regular monthly payments.

FILL OUT COUPON FOR ONE OF EVERY 10 COPIES OF THIS BOOK, IT GIVES FULL INFORMATION.

LEARN WIRELESS IN TEN WEEKS
Right In Your Own Home

The Age of Wireless Is Here

The experimental stage has passed. Wireless now equals in importance telegraphy, and telephony. It has assumed its place among the great commercial industries of the earth. So rapid has been the development and growth of wireless in recent years that there has been left in its wake a tremendous shortage of operators. Actually thousands upon thousands will be needed for permanent "peace time" positions offering wonderful opportunities for advancement:

No Previous Experience Necessary

You do not need any previous training or experience in order to become a successful Wireless Expert. By our practical ten weeks' Home Study Course you can quickly qualify for a good position at big pay. Many of our students have secured positions before completing the course.

Get Your Instruction From the Nation's Capital

Our Course Is Endorsed by Officials of the U. S. Government

The National Radio Institute, headed by authorities who have been closely allied with government training of students, has perfected an easily mastered course in wireless telegraphy whereby students are taught completely in ten weeks, either here in Washington at our large residence school or at home, by mail. Many of our students are ready to take up actual wireless work in much less time. The course is founded on actual practice, hence the rapid progress of the student.

Earn Up to $200 Per Month

In the short period of ten weeks we can make of you a wireless operator, a man with a profession, independent, and not subject to the rise and fall of wages in the labor market. Salaries are as high as $200 per month. We give you this training at home, by mail, in your spare time. It is not necessary for you to lose any time from your work to take the course. Then when you have received your diploma we help find you a good position.

Free Instruments to Every Student

In addition to text books, lessons and personal instruction, we send you a Home Practice Set consisting of a standard sending key and buzzer, and a Universal automatic wireless transmitting and receiving set. These instruments are free to every student. No other school can offer you what we do.

Pay As You Go Along With Your Lessons

Our plans of payment bring a wireless education within the reach of anyone who desires to learn. A small payment down and small payments twice a month enable you to earn the cost of your tuition while actually learning to be a wireless operator.

Wireless News Notes

The U. S. Shipping Board has recently announced an increase of nearly 30% in the pay of Merchant Marine Wireless Operators.

Nicola Tesla, world famous inventor, has recently perfected his Wireless Light, one of the wonders of the age. Another new invention has been perfected whereby wireless messages may now be sent underground.

Due to the recent perfecting of the Wireless Telephone, we expect to soon be able to communicate with our Home Study students by wireless.

Valuable Wireless Book FREE

Our booklet, "WIRELESS, the Opportunity of Today," gives you complete information in regard to our course, the quick and easy methods by which you can master wireless, and other important facts you should know. It is free. Just mail the coupon. No obligation whatever on your part.

TRANSMISSION OF LIGHT THRU WATER.

The comparative transmission of light thru varying depths of water is a problem that science until recently knew but little about. Now, thanks to Mr. S. L. E. Rose, of the General Electric Company's illuminating engineering laboratories, who describes his findings in the General Electric Review. Photometric readings were taken every six inches through the available range of 5/8 feet of water in the cylindrical tank in which the tests were conducted. The water used was Schenectady city water, which is clear artesian well water. Sea water would transmit much less light owing to the apparent blue or greenish tint it possesses which tints bespeak a fairly considerable amount of suspended matter and consequently increased opacity.

The accompanying graphic curve shows vividly the relative transmission of light from a Mazda lamp, fitted with waterproof connections. A table of constants is given in the article, together with a formula for computing the illumination intensity for different depths of water when the initial intensity is known. The present graph shows, however, just how rapidly the illumination falls off in water for any given initial illumination. The particularly interesting feature of the results from a practical standpoint is the very considerable cut-off of light produced by a substance apparently so transparent, amounting for a single foot (0.05 m) of water to 27.5 per cent. On this basis the transmission through 50 ft. (15.2 m) of water would be only about one part in 10,000,000 of the incident light.

The rapid decrease in the transmission factor with increased light in water coincides with the well-known facts that, for a so-called transparent medium, the ocean permits the penetration of daylight to but a surprisingly short distance below its surface and that fish native to the depths are blind or carry their own illuminants.

HAMMOND RADIO CONTROLLED BOAT SUCCESSFUL.

Army and navy experts have reported the device of John Hays Hammond, Jr., for radio control of surface craft to be sent laden with explosives against enemy ships a success, and predict similar results with submerged craft.

Secretary Baker wrote the House appropriation committee recently that the joint army and navy board was "convinced of the practicability of the control" of the surface craft, and added that there had also been demonstrations of the possibility of the control of a craft, completely submerged, except for an air in-take pipe.

Before finally deciding on the purchase of the patents for $750,000 the board desires further experiment with the submerged craft.

Construction of the submerged craft, which will be about 80 feet long by 7 feet in diameter, will take two years, according to Mr. Hammond, who told the committee he had spent ten years and $400,000 on his invention.

"The board considered the ability of the enemy to interfere with the control of the vessel by radio energy. Mr. Hammond's claims are that no interference can be had with the craft outside a radius of 100 to 150 yards from the source of the energy; that is, from the radio plant of a battleship, for example."

Major-General F. W. Cole said he had run the craft "all around vessels coming into the harbor at will." Mr. Hammond said an aviator after four hours' training on control, was able from a height of 9,000 feet and a distance of six or seven miles to exercise absolute control over the high-speed boat.

ELECTRIC SNOW MELTER FOR TRACK SWITCHES.

The electric snow-melter device for track switches here illustrated is purely and simply an electric heater enclosed in a 3/8 inch wrought iron pipe, 20 inches long. These heaters are placed between the ties, just under the rail. They are wired from a circuit as the amount and character of the supply current may vary, and a switch is placed in this wiring at some convenient point clear of the track. The current can be turned on as the snow storm starts by an employee as readily as an electric light. The heat generated does not melt.

The temperature in the heater rises about 100 degrees Centigrade in the first half hour and by the end of an hour is about 135 degrees Centigrade above the ambient temperature. This heat is not enough to set fire to anything but is sufficient to melt the snow.

EARN $35 TO $100 PER WEEK

As a Mechanical Draftsman

Thousands of Men Wanted

You can learn Mechanical Drawing at home in your spare time through our practical Home Study Course and qualify for Big Pay. We have placed hundreds of our students in good paying positions. Government departments and private concerns are continually calling upon us for our graduates.

Become a Chief Draftsman and get to the very top in this well-established and rapidly growing profession. The training given by the Columbia School of Drafting will give you just the knowledge you need to make good as a Chief Draftsman. No previous training is necessary. You can begin our course now and make rapid progress from the start under the Personal Instruction of the President of the School, Mr. Claffin, by mail. His carefully prepared lessons and personal letters of advice make each step easy and interesting.

Draftsmen Now Getting $35 to $100 a Week with big chances for better pay as the demand grows. All big engineering, construction and manufacturing projects must start and go through the drafting room before the workmen can commence. All such enterprises depend upon large numbers of draftsmen. Salaries are advancing steadily.

Drawing Outfit Free with Our Course.

As soon as you enroll you will be sent our drafting outfit for your own use through the course. This entire outfit will be yours to keep. You are not obliged to return it after completing the course.

Not Only a Correspondence School

The Columbia School of Drafting is probably the largest residence school in the country specializing in the training of professional Draftsmen. Our Home Study Courses are an extension of the same instruction as given locally.

Illustrated Catalog FREE

Simply fill in the coupon below, return it to us and we will send you free a copy of our illustrated catalog which tells all about our practical Home Study Course and how you may secure our instructions at once on easy terms so as to quickly qualify for one of the big positions open.

Send This Coupon Today.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
ELECTRICAL EXPERIMENTER

April, 1919

What is a "kilowatt" and "kilowatt-hour"? (Continued from page 897)

will give a constant reading of 80 kilowatts; in other words, for a speed twice as great the watt-meter will show a constant reading twice as high, whereas the watt-hour-meter reading will be the same for the same distance traveled.

Applying the formula to this example for a speed of 10 miles per hour and a power consumption of 40 kilowatt-hours, we get

$$40 \text{ Kilowatts} \times \frac{897}{40} = 40$$

Making the same run in one-half hour we get

$$\frac{40}{897/2} = 40$$

Dividing the total power consumed by one car in kilowatt-hours by the distance in miles, we get the power consumption in kilowatt-hours per car mile.

Applying the above terms to electric light, a 40-watt electric light is one that consumes electric power at the rate of 40 watts or 40 watts-hours per hour. A circuit having, say, twenty 40-watt lights in parallel will then consume electric power at the rate of 20 x 40 = 800 watts or 800 watts-hours per hour, or 40 watts-hours per lamp-hour. If

an electric power station charges you ten cents per kilowatt-hour you can burn one 40-watt lamp

$$1000 = 25 \text{ hours, or twenty 40-watt lamps}$$

$$1000 = 1\frac{1}{4} \text{ hours, for ten cents, since both conditions represent one kilowatt-hour.}$$

Something new in lamp guards.

A new departure in portable lamp guards is shown in the illustration of a split handle which can be quickly attached to a special expanded steel lamp guard supplied by the manufacturer. This portable successfully fills a demand for a substantial handle guard which does not need to be wired. The halves of the handle including the guard itself, open or close at the hinge at the bottom of the guard and can instantly be closed and locked around the socket at the end of any extension cord. The cord itself runs thru grooves in the handle.

The convenience of this new product will be appreciated by the motorist in his garage as well as in every factory, mill or warehouse because it permits light to be safely carried to dark corners, in stock lins, engine pits, etc. Fire danger is avoided and lamp users will readily see the advantage and economy, as the modest cost of the guard is quickly repaid thru prevention of lamp breakage.

Another "useless" Patent.

A Chicago woman has patented a shoe with an electric battery in the heel to supply a mild current to a wearer's ankle as a tonic. Another "useless patent!"

The photoelectric sensitivity of various substances.

SOME time ago an examination was made of various substances to determine their electrical sensitivity to light; and in the view of the fact that some of the results obtained are at variance with the measurements made by Case, it seems desirable to publish a summary of these observations, which were made at the Bureau of Standards.

Two of the herein described substances were examined for the change in electrical conductivity caused by the action of light upon them, and all of them were examined for photoelectric activity when they were charged to a negative potential in an evacuated bulb and exposed to light, reports Messrs. Cobblett and Emerson in the Journal of the Washington Academy of Sciences.

When the substances were examined for an increase in electrical conductivity, a potential of 2 to 6 volts was connected thru a resistance of zero to 1,000,000 ohms into a circuit containing a d'Arsonval galvanometer and the current was measured.

In most cases the substances were slightly conducting when not exposed to light, so that the dark current had to be annulled by joining a counter e.m.f. thru a resistance of 10,000 ohms to the terminals of the galvanometer. This counter e.m.f. was obtained by shunting across the circuit a resistance of 100 ohms which was in series with a cell of 2 volts and a variable resistance of zero to 70,000 ohms.

The source of light, when not otherwise

COLD WEATHER WON'T BOther YOUR STARTER

If you keep your battery charged up with an F-F BATTERY BOOSTER

CONNECT to any lamp socket without removing battery from car or breaking any electrical connections. Changes alternating to direct charging current, and will completely fill your battery over night.

The Private Garage type costs only $24.95 and comes complete with long pole and plug in any lamp socket in your home or garage. Also includes a charger to fill the battery and charging wires fitted with clips, to snap on the battery terminals.

CORE WIRE

We have been fortunate in securing thru auction several tons of guaranteed pure, double annealed Norway Iron Core Wire and are selling this wire to "Experimenter" readers

AT PRE-WAR PRICES 20cts LB.

This wire is just the thing for spark coils, transformers, etc., and it is, of course, a very much more superior product than the usual iron wire. We absolutely guarantee the quality.

If you ever thought of building a spark coil, transformer, blast Furnace, etc., this wire is the change you are looking for. It is stronger than iron wire and will support ten times the current. We know this is the only lot of Iron Norway Core Wire in the hands of any dealer at the present time, and none can be gotten until after the war.

We have only two sizes left:

26 INCHES Thickness about No. 21 B and S

36 INCHES

If either of these sizes should be too long we advise cutting the wire down yourself by means of shears. It will pay you to do so as real Norway Iron Wire, sold by a few dealers last year, brought from 50c to $1 a pound. American core wire now sells at 2c a pound per pound.

As long as the supply lasts we offer this wire as described above to our customers at the very low price of 35 what a pound. Order at once.

ELECTRO IMPORTING CO., 231 Fulton St., N.Y.C.
specified, was a 10-c.p. carbon incandescent lamp, placed at a distance of 10 cm. from the substance under investigation. One disappointing feature of this investigation is that no substance was found which compared in sensitivity with the potassium photoelectric cell and with the selenium cell. Thomson. This metal was said to differ from the impure material, which is a liquid.

The results obtained proved disappointing. This metal was quite insensitive to light. When the cell was exposed to day-light the photoelectric current produced a deflection of only 4 mm., whereas similarly exposing a potassium photoelectric cell the photoelectric current was sufficient to give a deflection beyond the range of the scale.

Silver Sulfide. The sample examined was a thin flat strip, 6 by 10 mm. in area, to one side of which was formed the negative electrode of a photoelectric cell (evacuated glass bulb about 5 cm. diameter with a ring of platinum wire for the anode). It was connected to an electrodynamometer, and the cadmium measured. The result of this measurement showed a very small current when exposed to day-light. The sensitivity was practically the same when exposed to day-light or to the standard incandescent lamp.

Tellurium. This specimen was examined in a rectangular block 3 by 1.5 mm. It was held by compression between copper electrodes. After the specimen was heated to redness, it was placed in a glass tube and a tellurium deposited upon a glass plate by cathode disintegration. Suitable terminals were attached to a sample 4 by 30 mm. No change in conductivity was observed when it was exposed to light.

Boleite. The sample of boleite [3PbCl (OH). CuCl(OH) + AgCl], from Boleo, Mexico, examined was a single rectangular crystal 3 by 1.5 mm. It was held by compression between copper electrodes. No change in sensitivity was noted when the crystal was exposed to daylight or to the standard incandescent lamp.

Stibnite. The size of one sample examined by the method described was attached to it by heating a copper wire to incandescence in a gas flame and bringing it in contact with the plate of stibnite. The standard carbon lamp caused a deflection of 5 cm. Stibnite may be considered as sensitive as boulangerite, to be mentioned presently, but the deflection drifted, due to the decrease in resistance with time already noticed by other observers.

Boulangerite. The specimen of boulangereite (3PbS. Sb. S.) from Irkutsk, Siberia, investigated was obtained from the Smithsonian collection. Several samples were examined. In one sample, 4 by 7 by 0.8 mm., the electrodes consisted of copper wires which formed the anode and the cathode was just described. The radiation from the standard lamp gave a deflection of 10 to 20 cm. Another sample, 1 by 1.2 by 2 mm., held by compression between two heavy electrodes of copper, when exposed to the standard incandescent lamp produced a deflection of 0 to 3 cm., which is comparable with the preceding when one considers the size of the exposed surfaces.

Altho this substance seems fairly sensitive, it is not apparent to be sufficiently so to justify an investigation of its spectral sensitivity with a view of using this mineral as a selective radiometer.

Jamesonite. (2PbS: Sb:S.) Smithsonian Institute.
collection, from Cornwall, England.) The sample examined (size 2 by 7 by 1 mm.) had the copper wire terminals attached by fusing the incandescent wire into the material. The standard lamp gave a deflection of only 1 to 2 cm., which seems to indicate that the material is not so light-sensitive as is boulangerite.

Mixtures of galena and stibnite in various proportions were melted in a crucible and poured upon a plate of metal. Several samples, 5 by 10 by 0.5 mm., were examined, but none of them gave any indication of light-sensitivity (change in resistance) when exposed to daylight or to the standard incandescent lamp.

Bismuthinite. Bismuthinite, Bi₂S₃, was obtained from the Smithsonian collection from Jefferson County, Montana. This is the most interesting specimen in the collection and almost every view of the diverse results obtained and the explanation offered thereof.

The sample of bismuthinite examined consisted of a non-homogeneous mass of acicular crystals, which was easily crushed into numerous fine needle-like crystals. The first sample examined was a small mass of crystals, 1 by 1 by 0.2 mm., which was pressed between two heavy electrodes of copper. When the crystal was exposed to the standard carbon lamp no change in conductivity could be detected with certainty.

A second sample, 3 by 6 by 1 mm., had the copper wire terminals attached by fusion, as already described. The e.m.f.'s applied were the same as for the preceding sample. When exposed to the standard lamp no change in conductivity was observed. These results were in agreement with those published by Case, who used a three stage Audion amplifier to detect the change in conductivity of the crystal. The foregoing experiments were repeated in the manner described by him. For this purpose the light from an acetylene flame shining thru a slit 2 by 10 mm., was focused upon the crystal by means of a triple achromatic lens, 6 cm. in diameter and 18 cm. focal length. The light was interrupted by means of a sector disk having 15 openings and operated by means of an electric motor, the speed of which could be varied. The usual speed gave 240 interruptions per second. The crystal was connected to a three stage Audion amplifier and telephone receiver. A crystal of selenium, whose conductivity had been found to be a good note, but the samples of boulangerite and jamesonite, which were by previous tests were light-sensitive, did not give a musical sound in the telephone.

The sample of bismuthinite with electrodes sealed on produced no audible note when exposed to light.

At least a dozen samples of bismuthinite held by compression, compression by hand, and electrodes were examined in connection with the amplifier. Of this number only two samples appeared to be light-sensitive. One sample produced only a faint humming sound in the telephone receiver. The second sample produced a loud note in the telephone. The sound was the loudest when the crystal was exposed along the line of contact with the copper electrode. Covering the crystal with red glass did not reduce the loudness of the note very much, indicating that the effect is due to heating of the material. Unfortunately, this crystal was crushed while under investigation; prolonged tests on other samples gave negative results as regards the production of sound.

In view of the fact that the tests made with a sensitive galvanometer failed to show an increase in sensitivity, it seems highly probable that the bismuthinite was exposed to light, it appears that the change in conductivity which was observed when a certain specimen was exposed to intermittent flashes of light (photoflash or, rather, radiophone) is
the result of a thermal change within the crystal, or perhaps a change in the contact resistance at the electrodes. In this connection the following experiments on thin strips of metals are of interest.

Platinum and Gold. In conclusion it is of interest to record the results obtained when using thin blackened strips of platinum and of gold-leaf as radiophones, by connecting them thru a battery to an amplifier.

These blackened strips were warmed intermittently by exposing them thru a rotating sectored disk to the acetylene flame, as already described.

When a sensitive platinum bolometer receiver was used as a radiophone, the sound produced in the telephone was not very audible. This no doubt was due to the great heat capacity of the material which prevented the rapid alternations in resistance and hence in the current, from being of sufficient magnitude to affect the telephone receiver.

Using a lightly smoked strip (6 by 2.5 mm.) of gold-leaf, the ends of which were clamped between thin (0.02 mm.) strips of tin, the sound produced in the telephone receiver was as loud as was observed in the photophone made of selenium.

This device was mounted in a glass bulb which could be evacuated. As was to be expected, there was no marked difference in the intensity of the sound produced when operated in air and in a vacuum.

In the gold-leaf radiophone as used, the limit of audibility was attained for a light (radiant power) intensity of 4.8 x 10^-5 watts. Using a larger receiver and amplifier and a larger current (which was 0.12 amp. in the present tests) thru the receiver, the sensitivity could be greatly increased.

MENTAL TELEPATHY—A SIMPLE CONCEPTION OF PSYCHICAL ACTIVITY

By Dr. H. Merlitz

In the September issue of the ELECTRICAL EXPERIMENTER there appeared an extremely interesting article by Dr. A. Abrams on Thought Transference and Other Phenomena. Altho he gave many interesting experiments he did not show the relationship of this theory to the rather obvious physical theories. It is the author's intention in the present article to present an explanation for this remarkable phenomenon.

We know very little in regard to the functioning of the human mind. We have practically no insight into the mechanism of thought and memory. We know, however, that the brain in function requires nourishment. Thus it follows that any operation of the brain is accompanied by the absorption of a certain amount of energy. However, contrary to ordinary laws, in storing a thought and in subsequently recalling it, energy is absorbed. These two processes are the reverse of each other, and it would naturally be supposed that in remembering energy would be destroyed.

To commit a thought to memory we repeat it several times, each successive repetition requires the expenditure of a certain amount of energy. Thus we say that the energy expended after a number of repetitions equals:

\[ E_1 + E_2 + E_3 + \ldots + E_n \]

Now when we remember it the process is the reverse, which gives us \((E_1)^n\) which would equal \(E_1\), which means the addition of energy. Thus the act of remembering a fact more firmly implants it in the mind.

We may easily assume that there is a certain practical limit to the amount of effect that can be produced. This limit might be called the saturation of the brain. It would be reasonable to suppose from this that for each repetition or act of remembering the amount of energy stored is less than that of the preceding one, decreasing in geo-
**Men Wanted for Airplane Industry**

Wonderful opportunities —great scope for advancement —and big pay. Hundreds of applicants to the industry. This does not mean actual flying, but in the field of the testing of the branches of the industry. It is the coming profession—the future means of transportation. Airplanes are already being carried by airplanes. Factories are springing up everywhere. The men needed are trained in small classes. 

**Openings in Many Branches**

You can get into this profession while it is still at a very low level in its infancy as a line of avigation you can step into a high-salaried position.

**We Guarantee Our Training**

We absolutely and unreservedly guarantee that our Home Training Course, if properly followed, will enable you to qualify as a good position as soon as you graduate. The course itself is written by experts in all fields of this work, and covers the entire field of practical mechanics. Every class is written in illustrated so clearly that you cannot fail to understand it even if you are a stranger to the subject. Then if you are not satisfied you need not take one cent. We guarantee satisfaction.

**Prepare Now for a Big Future**

Only by specialized instruction can you expect to succeed in aviation or any line of business. Training alone will not fit you for a big job—and the only one that will fit you is the one that will pay you the coupon for Big Free Bulletin and Money-Back Guarantee.

**AMERICAN SCHOOL OF CORRESPONDENCE**

You wish for mentionning of “The Electrical Experimenter” when writing to advertisers.
interesting incident. He wished to make the appearance of a young lady appear to a lieutenant living several miles away. At the time of the experiment a visitor happened to be with the lieutenant, who is said to have seen the apparition also. Many instances are recorded in which persons were hypnotized at some distance. All of these phenomena can be easily explained by the brain wave theory.

Besides the transference of thought, both sympathy and affection may be the outgrowth of these radiations from the brain. Whether our capacity for the reception of these impulses is increasing with the evolution of man, cannot be ascertained directly. It would seem probable, however, that with our increase in education and civilization that consideration of this thought language may be found. Who knows but that the man of the future may find a practical application for this radiation from the brain, and a host of more delicately made creature may result who would effect mutual understanding by means of this mechanism yet but little understood.

MY INVENTIONS
(Continued from page 885)

travel at a rate of about one thousand miles an hour, impracticable by rail. The reader will smile. The plan was difficult of execution; I will admit, but not nearly so bad as that of a well-known New York professor, who wanted to pump the air from the earth to the temperate zones, entirely forgetful of the fact that the Lord had provided a gigantic machine for this very purpose.

Still another scheme, far more important and attractive, was to derive power from the rotational energy of terrestrial bodies. I had discovered that objects on the earth's surface, following the daily rotation of the globe, are carried by the same alternately in and against the direction of translatory movement. From this results a great change in momentum which could be utilized in the simplest imaginable manner to furnish motive energy in any habitable region of the world. I cannot find words to describe my disappointment when later I realized that I was in the predicament of Archimedes, who vainly sought for a fixed point in the universe.

At the termination of my vacation I was sent to the Polytechnic School in Graz, Styria, which my father had chosen as one of the best reputed institutions. That was the moment I had eagerly awaited and I began my studies under good auspices and finally resolved to pursue them.

My training was above the average, due to my father's teaching and opportunities afforded. I acquired the knowledge of a number of languages and waded thru the books of several libraries, picking up information more or less useful. Then again, for the first time, I could choose my subjects as I liked, and free-hand drawing was to bother me no more. I had made up my mind to give my parents a surprise, and during the whole first year I regularly started my work at three o'clock in the morning and continued until eleven at night, no Sundays or holidays excepted.

As most of my fellow-students took things easily, naturally enough I eclipsed all records. In the course of that year I past three nine exams and the professors thought I deserved more than the highest qualifications. Armed with their flattering certificates, I went home for a short rest, expecting a triumph, and was more surprised when my father made light of these hard-won honors. That almost killed my ambition; but later, after he had died, I was pains to find a package of letters which

$5. THE Boy's Electric Toys

The Boy's Electric Toys contains enough material to make and complete over twenty-five different electrical apparatuses without any other tools, except a screw-driver furnished with the outfit. The box contains the following complete apparatuses and articles, which are already assembled:

- Student's chronic plunge battery, current galvanometer, sound, telephone receiver, electric lamp. Enough various parts, wire, etc., are furnished to make the following apparatuses:
  - Electromagnet, electric cannon, magnetic pictures, dancing spiral, electric hammer, galvanometer, coil, box, for telephone receiver, condenser, sensitive microphone, short-distance wireless telephone, test storage battery, shock coil, complete telegraph set, electric riveting machine, electric buzzer, dancing lights, dancing telegraph, mysterious dancing man, electric jumping jack, magnetic geometric figures, phonograph, telephone. Everything can be constructed and accomplished by means of this outfit, two hands, and a screw-driver.

No. EX2002

E X P E R I M E N T E R S!

A Sample of What You Can Do With This Outfit

This outfit contains 114 separate pieces of material and 24 pieces of finished articles ready to use at once.

The outfit is a wonderful high pitch musical Note in the receiver, impossible to obtain with the waltz test buzzer. The Radiotone is built along entirely new lines. It is a complete musical instrument. The Radiotone is a single instrument consisting of a telephone and a high-speed, magnetic amplifier and a high-efficiency receiver, all kept in one box. A new and improved instrument is used to make the apparatus last practically forever.

Yes, the Radiotone is Silent. It is not a musical instrument, but a practical, home-made electrical instrument, which is nothing but a toy. It will not work like the big commercial instruments. Simply by setting the slide with the help of the waltz test buzzer, the Radiotone is built along exactly the same lines as the waltz test buzzer. No ordinary musical instrument is used, but a high-speed, magnetic amplifier and a high-efficiency receiver, all kept in one box. A new and improved instrument is used to make the apparatus last practically forever.

The “Electro” Telegraph is not a toy, but a practical, home-made electrical electrical instrument, which is nothing but a toy. It will not work like the big commercial instruments. Simply by setting the slide with the help of the waltz test buzzer, the Radiotone is built along exactly the same lines as the waltz test buzzer. No ordinary musical instrument is used, but a high-speed, magnetic amplifier and a high-efficiency receiver, all kept in one box. A new and improved instrument is used to make the apparatus last practically forever.

The “Electro” Codophone (Patents Pending)

What a remarkable instrument is and does.

ELECTRICAL EXPERIMENTER

MY INVENTIONS.  
(Continued from page 905)

the professors had written him to the effect that this was the last occasion on which the Institution would be killed thru overwork.
Thereafter I devoted myself chiefly to physics, mechanics and mathematical studies, spending a large amount of time in laboratories. I had a veritable mania for finishing whatever I began, which often got me into difficulties. Thereon I started to read the works of Voltaire when I learned, to my dismay, that there were close on one hundred large volumes in small print that I had to finish whilst drinking seventy-two cups of black coffee per diem. It had to be done, but when I had the last book I was very glad, and said, "Never more!"

My first year's showing had won me the appreciation and friendship of several professors, among whom was Professor Poehl, who was teaching arithmetic and geometry; Prof. Poehl, who held the chair of theoretical and experimental electricity, and Dr. All, who taught integral calculus and specialized in differential equations. This scientist was the most brilliant lecturer I have ever listened to. He took a special interest in my progress and would frequently remain for an hour or two in the lecture room, giving me proofs so clear to the point that I was justified in understanding them.

To him I explained a flying machine I had conceived, not an illusory invention, but one based on sound, scientific principles. It had been realizable thru my turbine and will soon be given to the world. Both Professors Rogner and Poehl were curious men. The former had a number of expressions of expressionism, and himself did there so there was a moment, followed by a long and embarrassing pause. Prof. Poehl, an original and thoroughly grounded German, had enormous feet and hands like the paws of a bear, but all of his experiments were skillfully performed with clock-like precision and without a miss.

It was in the second year of my studies that be received the dynamic formula from Paris, having the horseshoe form of a laminated field magnet, and a wire-wound armature with a commutator. It was connected up and I am not under any impression that it could be possible to have a motor without these appliances. But he declared that it could not be done. He had mastered of driver of electricity lecture on the subject, at the conclusion of which he remarked: "Mr. Tesia may accomplish great things, but he certainly never will do it."

I could not do this. It was equivalent to converting a steadily pulling force, like that of gravity, into a rotary effort. It is a perpetual-motion scheme, an impossible idea." But instinct is something which transcends knowledge. We have, undoubtedly, certain firmer beliefs that enable us to persist without logical deduction, or any other willful effort of the brain, is futile. For a time I wandered, impotent by the way, but suddenly convinced I was right and undertook the task with all the fire and boundless confidence of your.

I seized first picturing in my mind a direct-current machine, running it and following the changing flow of the currents in the teeth, and would have the alternator and investigate the processes taking place in a similar manner. Next I would visualize systems comprising motors and generators, and proceed them in various ways. The images I saw were to me perfectly real and tangible. All my remaining time was spent in intense but fruitless efforts of this kind, and I almost came to the conclusion that the problem was insoluble. In 1880 I went to Prague, Bohemia, carrying out my father's wish to complete my education at the University there. It was in that city that I made a decided advance, which consisted in detaching the commutator from the machine and studying in this new aspect, but still without result. In the year following there was a sudden change in my views of life. I realized that my parents had been making too great sacrifices on my account and resolved to relieve them of the burden. The American telephone had just reached the European continent and the system was to be installed in Budapest, Hungary. It appeared an ideal opportunity to redeem the pledged bond of friendship of my family was at the head of the enterprise. It was here that I suffered the complete breakdown of all the efforts to which I have referred. What I experienced during the period of that illness surpasses all belief. My sight and hearing were always extraordinary, and the various objects in the distance when others saw no trace of them. Several times in my boyhood I saved the houses of our neighbors from fire by the fact crackling sounds which did not disturb their sleep, and calling for help.

In 1889, when I was past forty and carrying on my experiments in Colorado, I could hear very distinctly thunderscalps at a distance of 550 miles. The limit of audition for a scientific man was scarcely more than 150 miles. My ear was thus over thirteen times more sensitive. Yet at that time I was, in spite of this, not to speak, in comparison with the acuteness of my hearing while under the nervous strain. In Budapest I could hear the ticking of a watch with three rooms between my ears and the time-piece, flying alighting in a table in the room would cause a dull thud in my ear. A carriage passing at a distance of a few miles fairly shook my whole body. The whistle of a locomotive twenty or thirty miles away made the bench or chair on which I sat vibrate so strongly the seat was unbearable. The ground under my feet trembled continuously. I had to support my bed on rubber cushions and rest at all times. The roaring noises from near and far often produced the effect of spoken words which would have frightened me had I not been able to resolve them into their accidental components. The sun's rays, when periodically intercropped, would cause blows of such force on my face that I would sometimes have to look up to summon all my will power to pass under a bridge or other structure as I experienced a crushing pressure on the skull. In the desire of a last effort I could detect the presence of an object at a distance of twelve feet by a peculiar creepy sensation on the forehead. My pulse varied from a few to two hundred and sixty beats and all the tissues of the body with twitching and tremors which was perhaps the least to be endured by a physician who gave me daily large doses of Bromid of Potassium pronounced my malady unique and incurable. It is my eternal regret that this illness was not proffered of me capable in psychology and physiology at that time. I clung desperately to life, but never expected to recover, and to believe that so hopeless a physical wound could ever be transformed into a man of astonishing strength and tenacity, able to work thirty or forty years without a day's interruption, and find myself still strong and fresh in body and mind? Such is my case. N power is left to me, and to continue the work, and the assistance of a devoted friend and athlete accomplished the wonder. My health returned and with it the vigor of mind. In attacking the problem again I almost regretted that the struggle was soon to end. I had so much energy to spare. Whenever the task it was not with a resolve such as men often make. With me it was a sacred vow, a question of life and death. I knew that I would perish if I failed to solve the battle

(Continued on page 909)
MY INVENTIONS.
(Continued from page 907)

was won. Back in the deep recesses of the brain was the solution, but I could not yet give it outward expression. One afternoon, which is etched in my recollection, I was enjoying a walk with my friend in the City Park and reciting poetry. At that age I knew the entire book heart, word for word. One of these was Goethe's "Faust." The sun was just setting and reminding me of the glorious passage:

"Se rickt auf, der Tag ist überlebt, Dort eilt sie hin und fürdert heut's Leben. Oh, dass kein Flügel mich vom Boden hebt Ihr nach und immer nach zu streben!"

Ein schöner Traum tuidessen sie entweicht, Ach, zu des Geistes Flügel wird wohl Kein körperlicher Flügel sich gesteigen!"

As I uttered these inspiring words the idea came like a flash of lightning and in an instant the truth was revealed. I drew with a stick on the sand the diagrams shown six years later in my address before the American Institute of Electrical Engineers, and my companion understood them perfectly. The diagrams were wonderful, but sharp and clear and had the solidity of metal and stone, so much so that I told him: "See how these ideas reverberate through my mind. I cannot begin to describe my emotions. Pygmalion seeing his statue come to life could not have been more deeply moved. A thousand ideas were in my head which I myself stumbled upon accidentally I would have given for that one which I had wrested from my brain against all odds and at the peril of my existence.

"The glow retretas, done is the day of toil; It black into a few fields of life existing; Ah, that no wing can lift me from the soil. Upon its track to follow, follow soaring!"

A glorious dream though now the glories fade. Arise the wings that lift the mind to flight. Of wings to lift the body can be bestowed."
It contains the following 44 chemicals:
- Alum \(\text{Al}_2(\text{SO}_4)_3\)
- \((\text{NH}_4)_2\text{SO}_4\)
- Antimony (powdered) (Sb)
- Ammonium Acetate (\(\text{NH}_2\text{CH}_3\text{COO}\))
- Ammonium Carbonate (\(\text{NH}_4\text{CO}_3\))
- Ammonium Chloride (\(\text{NH}_4\text{Cl}\))
- Barium Chloride (\(\text{BaCl}_2\))
- Boric Acid (\(\text{H}_3\text{BO}_3\))
- Bromine (\(\text{Br}_2\))
- Calcium Chloride (\(\text{CaCl}_2\))
- Calcium Oxide (\(\text{CaO}\))
- Calcium Sulphate (\(\text{CaSO}_4\))
- Charcoal (\(\text{C}\))
- Copper Sulphate (\(\text{CuSO}_4\))
- Ferric Sulphate (\(\text{Fe}_2\text{SO}_4\))
- Ferrous Sulphate (\(\text{Fe}_2\text{SO}_4\))
- Glycerol (\(\text{C}_3\text{H}_5\text{OH}\))
- Hydrochloric Acid (\(\text{HCl}\))
- Iodine (I)
- Iron Chloride (\(\text{FeCl}_3\))
- Iron Oxide (\(\text{Fe}_2\text{O}_3\))
- Lead Acetate (Pb \(\text{C}_2\text{H}_3\text{O}_2\))
- Nitric Acid (\(\text{H}_3\text{NO}_3\))
- Perchloric Acid (\(\text{H}_3\text{ClO}_4\))
- Phosphoric Acid (\(\text{H}_3\text{PO}_4\))
- Sodium Acetate (\(\text{Na}_2\text{C}_2\text{H}_3\text{O}_2\))
- Sodium Borate (\(\text{Na}_2\text{B}_4\text{O}_7\))
- Sodium Carbonate (\(\text{Na}_2\text{CO}_3\))
- Sodium Chloride (\(\text{NaCl}\))
- Sodium Nitrate (\(\text{NaNO}_3\))
- Sodium Phosphosphate (\(\text{Na}_3\text{PO}_4\))
- Sodium Sulphate (\(\text{Na}_2\text{SO}_4\))
- Sodium Nitrite (\(\text{NaNO}_2\))
- Stannous Chloride (\(\text{SnCl}_2\))
- Sulphate of Nickel (\(\text{NiSO}_4\))
- Sulphide of Zinc (\(\text{ZnS}\))
- Sulphuric Acid (\(\text{H}_2\text{SO}_4\))
- Tin (Granulated) (Sn)
- Zinc (Metal) (Zn)
- Zinc Carbonate (\(\text{ZnCO}_3\))

The following apparatus are furnished:

- One Standard Wash Bottle
- One Alcohol Lamp
- One Conical Glass Measuring Flask
- One Erlenmeyer Flask
- One Glass Funnel
- One Delivery Tube
- Six Assorted Test-Tubes
- One Test-Tube Holder
- Ten Sheets of Filter Paper
- One Glass Dropper
- One Spatula Measure
- Glass Tubing
- One book containing Treatise on Elementary Chemistry and 100 Chemical Experiments to be performed with this outfit.

We present herewith to our friends our new E. I. Co. Chemical Laboratory which contains real chemicals and apparatus to perform real chemical experiments. This outfit is not a toy, put up merely to amuse, but a practical laboratory set, with all the chemicals, apparatus and reagents necessary to perform real work and to teach the beginner the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

**DESCRIPTION OF THE OUTFIT:**

The outfit consists of forty-four (44) chemicals all C. P. (chemical pure) put up in appropriate wooden boxes, glass bottles, and hermetically closed jars. The acids are put up in glass bottles, with ground-in glass stoppers and there is a sufficient quantity of chemicals supplied (mostly one to two ounces) enough to make dozens of experiments with each. See list of Chemicals herewith.

The apparatus furnished are all of the best obtainable make and of standard laboratory size and shape. A list of the 17 pieces of apparatus furnished with this outfit is printed below herewith.

The instruction book is a real Chemistry Course for the Beginner. Some of the contents are: Division of Matter; This is a Treatise on Elementary Chemistry and deals with the theory of the Elements, Molecules and Atoms, etc. Chemical Nomenclature. This explains in simple language the derivation of the chemical names of the Elements and their compounds. There is a chapter on Laboratory Operations; Glass Working; First Aid; Fire Extinguishers; Experimenters' Aphorisms, etc.

A good part of the book is devoted to Weights and Measures. The Metric System, the English system and the U. S. System are fully explained.

The following tables are furnished: Symbols and Atomic weights of the Elements; Measures of Weights, Volume, Capacity and Length; Per Cent solutions; Conversion of Measure expressed in parts; Poisons and their antidotes; Technical and common name of chemical substances; Formulas for Cleaning various substances, etc., etc.

Among the 100 Experiments are:

- How to make chemical tricks; How to make invisible and magic inks; How to test flour; How to test soil; How to Make Chlorine Gas and smoke (German War Gas); How to bleach cloth and flowers; How to produce Oxygen and Hydrogen; How to make chemical colors; How to test Acids and Alkalis and hundreds of interesting hints and formulas.

**The price is still $5.00**

Shipping Weight 10 lbs.

PRACTICAL CHEMICAL EXPERIMENTS.

(Continued from page 894)

tee, and must furnish certificates of good character. These selections have been handed down faithfully from one generation to another for hundreds of years.

QUESTIONS AND ANSWERS IN CHEMISTRY.

Standard Soap Solution.

Q. 1. Roy Munson, Henrietta, Okla., wants to know the method of preparing the Standard Soap Solution as mentioned in the lesson on water testing of the "Experimental Chemistry" text.

A strong solution of this soap is first prepared by rubbing together in a mortar, 75 grams of the so-called "head plaque" (which consists principally of fats and bases), which may be obtained from your druggist, and 20 grams of dry potassium carbonate. When the two are thoroughly mixed a small quantity of methylated alcohol is added, and the mixture worked to the consistency of a thin smooth cream. More spirit is then added, and the contents of the mortar rinsed, using more of the spirits for this purpose. This is then collected in a bottle and the solution made to settle. The clear liquid is decanted off thru a filter, and the sediment finally washed upon the filter with more spirit. The volume of the liquid may be made up to 200 or 250 cc., by adding a mixture of equal volumes of spirit and water.

Solvay Process.

A. Sodium Chlorid, commonly known as table salt, is the source from which the sodium alkalies are derived. The starting point of this process is therefore salt—the really strong salt brine. If you open a bottle of ordinary smelling salts and inhale the vapor, you will immediately recognize the ammonia gas of the Solvay process in the form of bird's nest, just as it is contained in the common household ammonia. The third and last noble ammonia gas, the gas which is used to make soda water. For the purpose of this process it is obtained in large quantities by heating the salt stone to a high temperature. Thus we see that Salt, Ammonia and Carbonic acid gas are the three fundamentals upon which the process is based.

The salt brine is saturated with ammonia gas and carbonic acid gas is then blown into the solution of ammonia in the brine. The brine does not take place in one step, but the final products are Sol-ammonic and crude bicarbonate of soda. The crude bicarbonate of soda separates out as a white powder and the sal-ammoniac remains dissolved. The ammonia takes the place of the sodium in the salt, and the sodium carbonate with water and carbonic acid to form the well-known baking soda (Sodium Bicarbonate).

This is separated from the liquids by filtration. It is then necessary to prepare this for a commercial product by heating it in a furnace where it loses all its water and carbonic acid gas. The product is now known as sodium carbonate, or soda ash, the finished product of the Solvay process, and the starting point for other forms of sodium alkalis which are coming from the filtration process contains the sal-ammoniac, and this is distilled with water to remove the ammonia to be used over again—no ammonia remains in the soda.

ELECTRICAL EXPERIMENTER

Mercury Vapor

Q. 3. Gordon Jones, Jr., Cordele, Ga., wants to know how Mercury Vapor is obtained.

A. Under a pressure of 200 mm., mercury boils at 357.25 degrees C., giving off a colorless vapor. Mercury gives off vapor at ordinary temperatures, and a gold leaf suspended over mercury in a stopped bottle, gradually becomes white upon the surface, owing to its amalgamation with the mercurial vapor. This vapor is poisonous, giving rise to salivation, such as loosening of the teeth, etc.

Buttermilk in Butter.

Q. 4. Theodore Coughlin, Rochester, N. Y., wants to know why buttermilk is objectionable in butter.

A. Buttermilk is very objectionable as it begins to decompose almost immediately, and sets up fermentation, in the butter itself. See article at head of this month's "Chemistry Department."

BACK NUMBERS CONTAINING "EXPERIMENTAL CHEMISTRY SERIES."

The "Experimental Chemistry" series, by Albert W. Wilsdon, started in the June, 1916 issue of the ELECTRICAL EXPERIMENTER and has continued since that date. Prices on the back numbers containing these respective lessons, many of which have been of the greatest value to High Schools, Normal Schools, and University Scholars, as has been proven by many letters which we have received from readers of all classes, will be further reduced upon the purchase of stamped and addressed envelope. If you wish a first-class and clearly explained treatise on Experimental Chemistry, procure all of these lessons and bind them together. Many valuable and original tables and formulas are included in these lessons which the author has found of particular value to him in his commercial experience as a chemist.

SCIENCE IN SLANG.

(Continued from page 885)

one way only where the electrodes are of unequal temperature. With the audition, music has even been transmitted with the help of a barometric wave and the miles, with a clever man at the adjusters, a long dash can be construed into a melody. An absolute flat is a Z sharp on a piano. In other words, you would be unable to hear it. As yet they have not got it down so that they can run the sound waves into the visual strata and make you "See Me What I Am To-day, Now Aren't You Satisfied?" evolve into a likeness of Bill Hohenziemers's "They Are Wearing Them Higher in Hawaii" into an X-ray.

"Fefi, De Forest and Marconi do not hold the whole stage in the wireless field. Prof. Fessenden has bushes of patents in the Pat. office on the stuff, and there are a lot of other guys who have earned the price of a meal from some little thing that makes particular use of audionuts."

POPULAR ASTRONOMY.

(Continued from page 869)

eye. The play of auroral lights around the poles is plainly visible and the earth's atmosphere reflects a rim of light to the moon at the poles of this New Earth. Owing to the lack of atmosphere at the poles, there is no diffusion of light and the earth therefore stands out in sharp contrast to a sky of icy blue, as in which the solar corona (Continued on page 912)

Fig. 7.—Position of Earth, Venus and Sun at Time of Observation at Opposition.

“IT PAYS TO READ "E. E." ADVERTISEMENTS"
and the stars appear even in the lunar day. To one equip an opera glass on the moon any of the wonders and beauties of our planet would be revealed; the shadows of our lofty mountain peaks would be seen falling across the adjacent plains and passing rain or snow storms would temporarily veil certain portions. Were our most powerful telescopes on the moon we could easily distinguish small islands and lakes and cities, as well. All objects five miles or so in diameter would be well within the reach of our great telescopes and we can imagine that the lunar inhabitants would spend a considerable portion of their time in attempting to solve the nature of many mysterious markings that come and go over the face of their nearest neighbor. It is indeed a pity that the opportunity to study a living planet at close range is granted to a world devoid of all forms of life while the great telescopes of our own planet sweep searching after a barren mass of lifeless rocks presenting no signs of growth or decay, a desolate and uninhabitable waste.

We have considered how our planet appears to the two other planets that are most likely to be the abode of life, Venus and Mars, and how it would appear if seen from our satellite the moon. It will not take much more consideration to see how we would appear from the major planets—Jupiter, Saturn, Uranus and Neptune. The greatest possible distance the earth could depart from the sun viewed from Jupiter would be a little less than twelve degrees. Mercury, as we know, is not an easy planet to observe, yet it departs at times nearly thirty degrees from the sun. Moreover it is so near to the earth that when it is seen near its elongation it appears as a bright first magnitude star. Our planet earth on the other hand is so distant from Jupiter that it would be invisible to the naked eye seen against a black sky. When we consider that it never gets more than twelve degrees from the sun under the most favorable circumstances as viewed from Jupiter and must therefore always be searched for in the light of the sun's rays we see the hopelessness of expecting to see our planet earth from the distance of Jupiter; we would find that our little planet earth was not only a most elusive little body but also quite uninteresting when found. It would appear only as a very small half moon with a suspicion of a few dark shadings here and there. As we travel outward from Jupiter to the planets Saturn, Uranus and Neptune our interest in the little planet decreases rapidly. It appears to shrink more and more in size in the telescope until at the distance of Neptune it has become so tiny and so near to the sun that it is hardly worth a search in the telescope.

(Next installment will appear in the May number.)
ELECTRICAL PATENT ADVICE

Edited by H. Gernsback

In this Department we publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Regular inquiries addressed to "Patent Advice" cannot be answered by mail free of charge. Such inquiries are published here for the benefit of all readers. If the idea is thought to be of importance, we make it a rule not to divulge all details, in order to protect the inventor as far as it is possible to do so.

Should advice be desired by mail a nominal charge of $1.00 is made for each question. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

NOTICE TO CORRESPONDENTS

Questions on Patent Advice are answered in this department every month, and naturally each question must take its turn. We have received so many letters during the past months that it is absolutely impossible for us to answer them all in the "Experimenter." Thus, for instance, the answers appearing in this issue are of letters going back as far as July, 1918. We would therefore ask our correspondents to bear this in mind, and if an answer is wanted quickly, correspondents should make themselves acquainted with the rules printed above.

Angle Finder.

(305) Geo. E. Zeigler, Urbana, Ohio, submits a device which he calls an angle-finder. It is an instrument to enable a surveyor to determine the degree of any angle. Such an instrument could be used in constructing buildings, bridges, or any other construction, etc. Our advice is as follows:

A. In the instrument described, use is made of a spirit tube with the usual air bubble, and by placing the angle which is to be read off in a certain manner. This device itself is not new, and a similar one has been used on autos to read the percentage of the grade, and we do not think it would be possible for this reason to obtain a patent.

Submarine Shell.

(306) J. R. Pelt, Jr., Parkersburg, W. Va., has submitted a device which only explodes fifteen feet under water. Diagram submitted shows the electrical connections which are activated upon being raised by water, which makes a contact as soon as the shell comes within about 15 ft. under the water. We think a patent on electrical depth bombs of this kind would be better ones made which have been used freely in the war.

Steam Boat Brake.

(309) Otto I. Kirby, St. Vincent, B. W. L., submits an idea of a brake for steamers or boats. The idea is short in that it has large steel valves folded up against the body of a ship in normal position. When the boat is to be stopped, the valves automatically open up at right angles to the boat and the ship, thereby exposing an additional surface to the water, consequently must slow down.

A. This idea is a good one but unfortunately it has not been described before. Until our mind no patent can be obtained upon it today. We do not think the device works out in practice.

Grass Cutter.

(310) John C. Reno, Spring Brook, Wis., has an idea of an arrangement to clean out grass that grows over the sidewalks. The device is to be made of sheet steel and by having a triangular nose, in our correspondent's opinion, such a tool would clean out the grass very readily in the corners between sidewalks and grass.

A. While no doubt this device was well satisfactory, we think it would certainly be trouble if the road was composed of cobblestones for instance. Otherwise, we find no trouble with the device, and think that a patent can be obtained upon it.

Fire Truck Device.

(311) M. Dumbar, Lorain, Ohio, writes: "I wish your advice about a patent on an electrical device that will immediately start the engine of a fire truck. My idea is, as soon as the alarm rings it closes the circuit which starts the engine of the fire truck. Please advise if this idea is patentable."

A. Providing such a device can be made rugged enough, so that it conforms with the Fire Department's existing requirements, we believe that such a device should prove of considerable benefit, and that the Fire Department not have devices whereby the fire under the engine is started within a few seconds after the alarm has sounded.

U.S. PATENTS

Don't Lose Your Rights

Before disclosing your invention to anyone send blank form "Evidence of Conception" to be signed and witnessed. A sample form together with granted instructions will show you just how to work up your evidence and publish your rights before filing application for patent. Assistant registered patent attorneys we represent hundreds of inventors all over the U. S. and Canada in the advancement of inventions. Our schedule of fees will be found reasonable. The form "Evidence of Conception" sample, instructions relating to obtaining of patent and schedule of fees sent upon request. Ask for them—a post card will do.

ELECTRICAL EXPERIMENTER

April, 1919

NEW PULL SOCKET HAS CUR- 
RENT TAP.

In many cases it is desirable to connect an electrical appliance to the wall by means of a pull socket, and not to have it fixed to the wall by a wire. This is especially true in the case of a lamp, or other appliance, which is likely to be moved about; or in the case of a lamp, which may be used in any part of the house, and which is likely to be carried about from one room to another. The new pull socket is a small, self-contained, and portable device, which can be easily carried about and which can be used in any part of the house. It is a combination pull socket and plug receptacle built into a single compact unit, which is compact, and which can be carried about with ease.

The pull chain controls the current to the lamp socket, and the terminals of the receptacle are in the side of the body of the appliance. The appliance is continuous in circuit.

An advantage of this type of socket is that it eliminates the annoyance of the long cord running from the appliance to the outlet. By means of the new fitting, current can be supplied directly below the fixture and various other appliances, such as fans, lights, etc., can be used.

Are you using the Electrical Experimenter? It is the only practical periodical in the world for the experimenter. It is full of ideas and information that will help you to make things usefully. It is full of useful information, and form for properly designing your idea, free on request. Write today.

**STUDENTS ART MAGAZINE**, Dept. 441, Kalamazoo, Mich.
The "Room Service", as it is called in all modern hotels, and which covers the serving of meals in rooms, is very carefully worked out, in the "Pennsylvania" and the "French-fried" hotel. The "Pennsylvania" system works out in this fashion: Suppose for a moment you are the guest, and that you decide to have breakfast served in your room. As soon as you mention the word breakfast to the telephone operator and give her your order, she writes it down on her memorandum pad, and as soon as your order is written, it is put on the telegraph transmitting plates. Then two important things immediately happen—two telegraphs, reproduce in writing your exact order, and, from coffee to cigars, one telegraph announcing your order in the "room service" kitchen in the basement, and the other one telegraph connected to the same circuit, but situated on your room floor, reproduces the order in writing before the "floor clerk" on your floor, and this is the first notice that she receives that you have ordered a meal. The system works out very beautifully in this way, and gives the greatest expedition possible to rapid service. Each floor has its own service pantry, which contains all ordinary things such as bread and butter, and which is replenished daily. In this room there are also automatic high speed electric dumbwaiters communicating with the "room service" kitchen in the basement, as soon as any broiled meat, such as chops, steaks, etc., are prepared in the main kitchen, they are whisked skyward and delivered on your floor. As soon as the dumbwaiter reaches the floor, a buzzer starts signaling the fact, buzzing continuously until the delivery man at the dumbwaiter station removes the door, and the door closed, after which the dumbwaiter is dispatched Kenneth, by means of a special truck, one for each of the 19 floors, and the kitchen service dumbwaiters may be dispatched roof-and-roof and called to stop at any time, and the door is also locked on the plug in the jack corresponding to that particular floor. When the meal is ready, one of the room service waiters, when his name appears on your floor serves the meal in your room, and invariably of course, a table has to be provided for this purpose. Eventually, we presume that the "room service" idea will be extended and amplified, so as to permit the serving of meals, albeit this is questionable for the reasons already stated.

Returning toward the lower regions of the building we entered the building’s long hall, running long one of the lower floors, and we inspected the children’s open-air playground, arranged in one of the lower large rooms, which was several, and ended up this part of our inspection trip, by looking over the large ladies and gentlemen’s "plunge", provided with large deep pools, and every convenience imaginable. The "plunge rooms" in general are provided with steam rooms, hot rooms, massage and silent rooms, dressing rooms, etc., which the women’s plunge apartment contains specially fitted dressing and rest rooms, as well as a manicure and hair-dressing parlor and chiroprist.

Just as we were leaving the plunge rooms, we were startled by seeing two nursing maids passing down the hall just ahead of us. Upon inquiry we found that the hotel management had made every effort to supply such personnel and to be conjured with when such a large number of guests are considered. Not only was it surprising that the hotel should include a "hospital", but it was more interesting that there is a physician always present. Thus the guests have always available hospital and medical attention for any emergency. Of course, for any protracted illness, the patient would have to be transferred to one of the regular city hospitals. One does not even have to leave the building in order to get a prescription filled, as there is a large and complete drug store on the street floor, which is accessible from the interior.

In various parts of the hotel, where the architects have planned for them, one suddenly bumps into unsuspected scenes of activity. On some of the lower floors, as well as in spare rooms on the roof, one finds carrying cases and decorators, shops, an up-to-date upholstery shop, yes, even a silver-plating room (for taking care of those precious pieces of silverware used in the dining rooms), employees’ club rooms, plumbers shop, etc., etc.

A few words may be said here concerning the elaborate kitchen equipment at these hotels; and we ask the manufacturers of such equipment to give us a revelation to see how cleverly the engineers who designed these departments have worked out their problems. For example, all the soiled dishes from the soiled dishes in the dining rooms are practically never touched by human hands, after once being removed from the dining tables. They are placed in metal carriers resembling large drap pans as soon as they pass the dinner room service door. Here they are placed on continuous moving platforms, which are kept moving at a constantly changing angle, so as to utilize the power of gravity, and eventually the dishes reach the dishwasher automatically, which is quite an establishment all by itself. The dishes are washed by plunging them into large tanks filled with steam and boiling water, and then out again. They are very soon as soon as he hits the tanks, and the dishes are then rinsed in other tanks filled with boiling water, which is so hot that the dishes are carried through the rinsing tank by the force of a stream of water, and the water vapor remaining on them. The clean dishes are then delivered to another continuous moving platform, which takes them back to their respective kitchens. The scenes in these great kitchens are ones that have never been described before, and we visited this important department of the great hotel organization. Here we see dozens of Paris chefs preparing the various meats and cooking them. It would be a great revelation to any housewife to see how rapidly the cooking is accomplished. The dishes are distributed in the various ranges and stoves used for cooking the various foods, and there is a special kitchen fitted with all electric ranges and broiling stoves, which we termed the "home cooking kitchen". This kitchen is one of the features of the "Pennsylvania" and is in charge of the famous chef. Any guest who has gastronomic trouble or for other reasons may desire to have a piece of pie like "Mother used to make" with its full quota of gingersnaps, lemon pies and toothsome apples—can have just what his stomach craves. When the waiter visited the kitchen, it was near dinner time, and the chefs were busy cooking soups by the hundreds in the gigantic ranges, chops by the same number, and steaks by the dozen, not to mention French fried potatoes by the bushel. Other activities of the department include ice-cream making, pastry and candy making, etc., etc. One of the most wonderful sights in this important section of any hotel, and particularly in this giant of all hotels, where wagons of vegetables are kept, not to mention several auto-truck loads of meats and fish. Large, thoroughly ventilated refrigerators, keep the steam着他 and compressor plant operated by the hotel, maintain a constant degree of cold in them.

Of course, there are the usual wine cellars, one of which extends the whole block, not to mention large rooms filled with snow white linen, shining silver and glassware and crockery enough to stock an average department store.
SCIENCE IN SLANG. (Continued from page 911)

the wireless more of a success, but who have not had the public notified that they pulled a good show.

"Old Doc. Fleming got a good one in the form of a 'valve,' which is a lot like the audion. It was a close second in the patent office and only has first place by much writing and perspiration on the part of a wise old judge who weighed the proposition like a pair of assayer's scales."

"Then suddenly, when we kiss the dear old war good-bye, in drops old man Jimmy Rogers. He steps up on the platform, puts up his hand and says: 'Shi, boys, before we send up aeronautical magicies, see me! Nix on those aerial wires!' We say: 'Thehellosusy. Whazzamatter with old Jimmy?'"

"Not much," says Jimmy, 'except that aerials are all wrong. Besides you don't need 'em. Just you take a hundred feet of rubber covered wire cable and bury it three feet underground into a trench, savvy? Hook the loose end to what was once your aerial cable and presto, in cone messages loiter in and out on a tin roof. And you receive twice as far as before, AND the old girl static, who used to tease the life out of our aerials with bad, alone now is getting the war. Simple, if you know how!"

"I guess that is about all for to-day—now for tomorrow. We may be able to carry around in our pockets a telephone that will enable us to talk to our colored friend in Africa—when we are in Siberia or Sing-Sing."

"The present wireless is a great success—so was the Roman chariot, but the Handley-Page aircraft has it over the old go-cart in more ways than altitude.

"Where is the art of cultivation? We thought that we had it down like a scenario until Luther Burbank showed us that cactos did not have to have their stickers and the fruit pigeons that we wear on our coat lapels could aspire to the rainbow. Way back in the old ignorant days, when a gink thought that it was no worse to marry his sister and raise a colony than we consider a divorce or Wall street play, there lived an old bird who observed that a little home and so forth would not hurt a wheat stalk and that other growths were helped thereby. I don't remember the guy's name—it was so long ago—but it seems he was an Egyptian. I would not say for sure though.

"Now look how long ago it was when we got out of the land of slavery in the electrical game—there are a string of years ahead of us yet—perhaps some electrical Bur- banks will show up. Don't get it in your head I am slighting Edison, Tesla, Stein- metz, Marconi, De Forest, Fessenden, and others who now have the WATT under the microscope and wearing their glasses at that. What we have done had he possess a masochist gun or a telephone—what would Edison do with the observations and discoveries of the past? Now we are moving! Moving as men have never moved before!"

PREPARED TO DELUGE GERMANS WITH GAS.

Statements that America next spring would have thousands of German front with undreamed of quantity of poison gases, that Edgewood Arsenal thru gas production would have brought about the capture of Ypres, and that the lone would have had ten tons of mustard gas to Germany's one, and that our chemists had surprises of which German scientists never dreamed—all these were recently disclosed by the War Department.

Colonel Bradley Dewey, who was in charge of that section, said that a mask had been evolved which required no nose clip and no piece in the mouth. A man could wear it indefinitely and could sleep in it.
DO RADIO WAVES TRAVEL ABOVE THE EARTH OR THRU IT?
(Continued from page 822)

stalling later stations under such conditions, to examine very carefully the topography or rise and fall of the country over which this radio system was to operate. Fig. 3 shows a more ideal condition for the operation of a radio station in a valley, and one which has proven to be entirely successful in practice. Here the surface waves have a chance to follow the contour of the ground, as shown, and the antenna in consequence receives a full quota of energy from the waves as they pass across it. It is conceivable in the case illustrated at Fig. 4 that the etheric space-wave component at B, may become totally a space wave without a grounded foot, and this would account all the more readily for the station not receiving any signals.

Some very interesting experiments were made some years ago on the relative efficiency of ground antennae and those which were reported in the journal "Jahrbuch. Für Drahtlose Telegrafie und Telefonie", and the essence of these tests is illustrated diagramatically at Figs. 6 and 7. The investigators, Kiebitz, K. and W., working with such antennae, utilized one form composed of insulated conductors placed in an open trench, as shown in Fig. 6, and later he covered the trench over with boards and piled soil on top of it. The more soil he placed on top of the trench, the weaker the signals became, until finally none were received at all. This showed apparently that if wireless signals were to be received by an ordinary ground antenna, it must be placed in close proximity to the earth's surface, as I have already described in the opening part of this article, or else in a more or less shallow trench, the top of which is open and not covered with any conductive substance or the material. The diagrams, Figs. 6 and 7, show how the gliding composite waves, with their ground components, cut across the antenna wires in the open trench, while in the closed trench, the ground waves or "feet" glide over the raised contour of the soil as shown, and how the ground components, reaching but a short distance below the surface as previously explained, do not cut across the buried aerial conductors, and therefore no currents are generated in them, as the tests prove.

One way in which a submarine may pick up wireless messages is shown at Fig. 8. Here the composite radio waves glide over the water with their ground components, as shown by the dotted lines. Now, if the submarine trails a heavily insulated wire, as shown, the upper end of which is supported on two or more floats, then it naturally becomes possible for this wire to pick up energy from the radio waves travelling in the direction of the wire, and signals will be received. As mentioned above, it is also possible, that by having the floats partly weighted so as to keep the antenna wires a short distance below the surface of the water, that wireless messages can then still be picked up, due to the partial penetration of the grounded components of the waves into the water, in a readily apparent manner. It is very doubtful if the submarine will be able to pick up any radio messages, if it lies at any considerable depth in the water, below 50 feet, with the antenna wire trailing along behind it, as the penetration of the wave base has been shown to be usually but a few feet below the surface. Wireless messages is shown at Fig. 8. Here the composite radio waves glide over the water with their ground components, as shown by the dotted lines. Now, if the submarine trails a heavily insulated wire, as shown, the upper end of which is supported on two or more floats, then it naturally becomes possible for this wire to pick up energy from the radio waves travelling in the direction of the wire, and signals will be received. As mentioned above, it is also possible, that by having the floats partly weighted so as to keep the antenna wires a short distance below the surface of the water, that wireless messages can then still be picked up, due to the partial penetration of the grounded components of the waves into the water, in a readily apparent manner. It is very doubtful if the submarine will be able to pick up any radio messages, if it lies at any considerable depth in the water, below 50 feet, with the antenna wire trailing along behind it, as the penetration of the wave base has been shown to be usually but a few feet below the surface. Furthermore, when submerged in salt water, it must be clearly understood, however, that experiment as well as theory both show that the penetration into moist earth or water increases with increasing wave length. Hence it is that of late, as the wave lengths...
Make Your Wireless Apparatus Send Further
Last Longer and Work Better

The wireless amateur and experimenter is once more busy constructing apparatus for use the moment that orders go forward allowing amateur stations to open.

The kind of apparatus you used before the war doubtless answered your purpose nicely, but just consider the tremendous advancement made in the art during the past two years and you will appreciate your modern apparatus must contain several new types of equipment to bring it up to date.

DUBILIER MICA CONDENSERS

proved their real worth in the Navy, the Signal Corps, and as a part of the equipment of the fighting Airplanes both here and abroad since 1916.

You can now purchase a genuine DUBILIER MICA CONDENSER for your newest set for any voltage and capacity. They replace Leyden Jars with greater efficiency and without brush discharge and with negligible losses. They are compact and indestructible.

Made in any capacity and up to 1,000,000 volts. Special condensers supplied for experimental work.

Used in practically every Government installation. DUBILIER MICA CONDENSERS are now ready for your use.

Type A  .002—21000 volts $18.00
          .004—21000 volts  $20.00

Boys! You Can Make Your Own Electrical Apparatus
with the aid of these wonderful books

Home-made Electrical Apparatus

By A. M. Powell

Three wonderful big books, each full of just the sort of information you have been looking for and at a price within reach of your pocket book. Each volume is printed on heavy paper, contains 25 pages and over 60 illustrations, complete working drawings for making every sort of electrical apparatus. Written so that you can understand them. The price is only 25 cents per copy, practically the cost of publication. See partial table of contents below and order now. The supply is limited.

Vol. I contains wiring directions and directions for making all sorts of Static Machines, State Apparatus, Home-made Batteries, Storage Cells, Transformers, Rectifiers, etc.

Vol. II contains wiring drawings and directions for all sorts of Voltagens, Ammeters, Galvanometers, Batteries, Inductors, Dynamo Keys, Switches, Telephones, Static Machines, etc.

Vol. III contains wiring drawings and directions for making all sorts of Dynamo, Motors, Electric Kitchens, Missionary Lighting and Transmitting Apparatus, Tools Used, Wireless Telephone, Electro-lighting, Experiments, etc. etc.

Any of these wonderful books will be sent to you postpaid for 25 cents.

Get your wireless stations
In Readiness Now.
Be prepared and avoid delay.

DUCK's big 300 page Wireless and Electric Catalog is now, as it always has been, the largest and most complete and dependable Wireless Catalog published. Mailed for 12c in stamps or coin. Not sent otherwise.

Everything in wireless worth while is listed in this catalog. The experienced amateur will tell you to see our catalog before buying. You thereby insured against an unsound purchase. It is the Broen Light to guide you right in the selection of your wireless apparatus. No bigger or better values are obtainable elsewhere.

If you have our catalog No. 11, you have our latest catalog. Do not write for another. Send for a revised price list. It is yours for the asking.

THE WILLIAM B. DUCK CO., 230-232 Superior St., Toledo, Ohio

of the larger stations have been increased, these horizontal receiving antennae can be sunk deeper and deeper before effective screening is observed. Hence the period 'rediscovery' of the astonishingly efficient horizontal receiving directio antenna.

As far as I have heard the first use of the horizontal receiving antenna was at Block Island in July, 1903, where we connected the receiver direct to a telephone line running across the island from the wireless station towards the Point Judith (R. I.) transmitter. Fine land signals were thus received.

In 1905 I used a bare copper wire lying directly on the ground at New Haven, and then determined within a few degrees the direction of the transmitting station by swinging this wire around a circle, the center of which was the receiving instrument and ground stake. The signals were loud when the wire lay in the plane of the station, in either direction to or from the station—practically the same for both. But when at right angles to this plane of propagation nothing at all was received.

But to return to your editorial, "Wireless Around the World", it is highly unfortunante that the esteemed advertising pro-pensities of the Marconi interests should have made capital over this performance of their station in the year 1918, when similar performances had been on various occasions a matter of record for at least two years prior to that date.

I send below a news clipping sent to me back in 1916 by a wireless operator at Awarua, New Zealand, which is self-explanatory. I have received many communications from this section of the world, and fortunately, I have not felt authorized to publish, recounting similar "anti-podal" radio-transmission.

"In connection with Commander Creswell's statement regarding the reception at various Australian wireless stations of messages sent out by Naun and other places in Germany, it is stated that similar messages are received nightly at several of the New Zealand radio stations, especially Awarua, which is probably the best equipped in the Dominion. The distance from Naun to Awarua is about 12,000 miles, which, if it does not constitute an absolute record, is very near it. The secret of these remarkable results which is in less formidable terms 'transmitting to the World War' would excite world-wide interest, lies in the De Forest ultra-ant�ur receiver—one of the most wonderful devices of apparatus invented since Marconi's first experiments. Dr. de Forest is an American, who lives at New York. His 'ultra-ant�ur' has the power not only of receiving the far-flung waves, but can also be used as a wireless transmitter for the equipment has, as yet practically unexplored.'

In fairness to facts wherever an epoch-marking feat of this sort is accomplished, whether in science or discovery, I am sure you will agree that it is highly important that due credit should be given to the first performance and not to a repetition in which the same result was to be generally advertised years thereafter.

Perhaps your article lays unwarranted stress on the improvements which the Anderson alternator today enjoys over the arc transmitter. After witnessing what the big arc transmitters are doing in Europe, as well as in the United States, together with their simplicity and ruggedness and the facility with which any wave length can be instantly obtained, it is but natural that you might wonder whether the alternator will some day supplant the big arcs; at least, except in stations where one wave length only is required.
ELECTRICITY IN FAR-AWAY BOMBAY.

The great success with which the introduction of electric power from the generating station on the Ghats is being developed in Bombay is revealed by the report of the Tata Electric Power Supply Company. The energy now being supplied to motors in Bombay amounts to 48,000 horsepower. Thirty-six mills are receiving power, and only the difficulties arising from the war prevented development being more rapid.

THE HOW AND WHY OF RADIO APPARATUS.

(Continued from page 875)

In the proper manner for giving a good indication, it is well to mention that no matter which form of detector is used in conjunction with the wave meter, that the wave meter itself must be kept at a sufficient distance from the exciting circuit, no matter what its form or make-up, so that there shall be just sufficient current picked up by the wave meter oscillating circuit to give a clear indication in the detecting or indicating device. If the wave meter is held too close to the exciting circuit, then either long wave lengths or harmonics of various wave lengths may be heard, and an incorrect reading obtained.

For many purposes it is desirable and necessary to excite the detector so that it will radiate a wave length of known value, such as in various radio measurements, etc. Fig. 5, shows a circuit in which the variable condenser is shunted across the variable condenser of the wave meter as the diagram indicates. This arrangement will cause oscillations to be set up in the oscillatory circuit of the wave meter, and an auxiliary inductance can be placed near the wave meter inductance so as to link the two inductively, and thus transfer the energy electro-magnetically from the wave meter circuit to the auxiliary circuit, and which energy shall have a wave length of known value.

At this juncture, the matter of arranging the wave meter cabinet, and especially the variable condenser and its scales, etc. should be considered. In this connection we may refer to Figs. 7, 8, and 9, wherein several important and simplified methods of arranging the variable and condenser scales, especially direct reading scales, are given. Fig. 6 shows a method used by the writer for several years with good satisfaction. In the scheme the variable condenser scale is specially made up on heavy bristol board or celluloid, (or else hard rubber with the graduations scratched in with a scriber and then filled with Chinese white), and instead of having simply the angular spaces marked off in degrees, and then having to refer to a direction chart in the usual way, the corresponding wave length values for the coil are read off from the calibration chart (Fig. 9) and marked off on the scale as shown in Fig. 6. Then as the indicator attached to the variable condenser knob is moved over the scale, and by noting which inductance coil is in use at any moment, the corresponding wave length may be read off directly as soon as the maximum resonance point is reached in the detecting circuit.

The indicator, Fig. 6, comprises a piece of heavy sheet brass, soldered or otherwise secured to the shaft of the variable condenser, and to the center of the arm is cut to the form shown, with the two sides edges best out to retain a piece of ordinary glass. With a glass cutter, a straight line is scored across the center of the glass, and this may be darkened

MURDOCK Radio Receivers

Noted for their extreme sensitiveness and un-failing dependability. At the very reasonable prices, they are the best receiver value in the world.

Health In A Glass Tube

The interesting story of a man "too busy to bother" who appreciated perfect health, energy and vitality only after he lost it—and how he won it back in a startling way

BY FRANK HARTLE

YOU probably know dozens of people like my friend John Brainard. Strong, robust, healthy, he used to have a real bulldog for stamina, and a very likable fellow in spite of his entire lack of sympathy for sickness and sick people. He regarded sickness as a mark of weakness and had such faith in his own excellent health that he had about as much sympathy for sick people as, according to Mark Twain, David had for Jonah. If you happened to mention that you didn't feel extra well Brainard would say, as courteously as was absolutely necessary—"I'll be--but you could almost see the entire matter sail out of his other ear. Sickness and suffering were foreign to John Brainard and he couldn't understand it in other people. That was all.

But as Jos Billings once said, "Health is like money--you never know you have a good thing until you lose it." And quite suddenly John Brainard realized what real health is. Too much overwork, incessant hours, innumerable meals, and general inattention to his health finally "told on him." One day I went to his apartments and found him in bed with a severe attack of sciatica, but fuming with rage in spite of the intense pain. "Why should I have this?"—I've been as healthy as a horse all my life. Why should I be sick?—hang it, I won't be sick," and he jerked himself to a sitting posture only to fall back in pain upon the pillow.

For a week John Brainard lay in bed in intense agony. Those of you who have suffered from acute sciatica or rheumatism know what it is. The doctor came and went, but Tuesday and Friday when I called, John only said, with a weak attempt at his former cheerfulness, "Nothing doing, Frank. They haven't pushed the right health button yet. When will you fellows anyway who know something about a 'man too busy to take care of his health is like a mechanic too busy to take care of his tools.'"

Next day while at lunch with George Conrad, our mutual friend, I mentioned about John's still being so very ill. "Listen, Frank, old boy," he said, "I want you to be pre- sumptuous or anything like that and I certainly believe that the Doc will fix John up fine, but there's a treatment which entirely cured my wife of chronic neur- algia, and now it's bringing total cure to my cousin, another sciatic sufferer. I think if John would give it a trial it might help him some."

Ten minutes further conversation with Conrad convinced me and I went right over to John's home to "spring it." "John," I said quietly, as I tip-toed into his bedroom, "I've got the very thing. Conrad has given me some real facts about what electric violet rays are doing for people and I think—"

"Oh," be interrupted, "I don't know. I don't imagine it can help me."

"Of course you don't know. And you never will until you try. Now don't talk foolish, John, old scout. Won't you even believe your friend? If this violet ray treatment has proved what it is."

And then I went on to tell him all I had learned about the treatment—how it had been invented by the great Tesla in 1890, how it was being used with wonderful success by eminent physicians all over the world, how he could use it on himself and it wouldn't shock him like electricity in other forms, how it would surely at least help his own sciatica when it had cured other folks' sciatica, neur- algia, hay fever, asthma, neuritis and dozens of other diseases, and finally I told him how it would bring back to him his old "pep," vigor, and "knock-em-dead" vitality. Then John rolled over and said, "All right, if it brings me out of this blamed bed a well man I'll swear by it for life. Cart in the dynamo, or whatever it is."

"It's nothing of

"When I ran that glass tube over my 'hide'," said John, "it felt just like a local anaesthetic on a wild tooth."

Now, through the Violetta, you can have in your own home, the wonderful violet-ray treatment—curing as easily as givng a glass of water—by the North American specialists and beauty specialists throughout the country. Now you can rid yourself of Chilblains, Cold, Colds, Constipation, Dandruff, Deafness, Eczema, Eye Diseases, Hay Fever, Headache, Goitre, Insomnia, Lumbago, Nervousness, Neu- ritis, Obesity, Paralysis, Piles, Pimples, Py- othermia, Rheumatism, Skin Diseases, Sore Throat, and many other ailments.

Multiply your bodily health—vitalize your nerves—double or treble your energy and vitality. Sleep better, increase your strength, improve your appetite and digestion. Soothe your nerves, reduce or increase your flesh, toward and strengthen the muscles. Identify your complexion. All with the Violetta.

Trixie Frigiana, the famous actress, says, "Cheerfully will I add my praise for Violetta. It's the best 'pain dared instrument' I've ever had the good fortune to find. It's wonderful. I cured my brother of neuritis. As for myself, I use it for facial treatments and general massage. I've found it very much for it." Frank Borzzone, of Seat- tle, Washington, says: 'I purchased the Violetta for my wife who was suffering from an acute attack of sciatica. From the very first treatment it induced peace- ful rest and she is entirely well now.' Scores of letters like these are received each day.

The Violetta is not a vibrator. It is a machine that contracts the muscles; it does not shock—it does not pound the muscles—it is absolutely painless.

Eminent physicians from all over the country apply the Violetta with wonder- ful results. Dr. Bert H. Rice, of Vinton, Iowa, says: 'I have good results with the Violetta.' Dr. Daniels, Lisbon, North Dakota, says: 'Have used the Violetta in such cases as Goitre, Bronchitis, Pleurisy, Nervousness and neuritis and found it very beneficial. In fact, I would not be with- out it in my office.' Dr. B. G. Duncan, Ke- wanne, Ill., says, 'The Violetta is the finest thing I ever used to relieve congestion in any part of the body; and to relieve pain. Treatments are so pleasant that all of my patients like it.'

Write for this interesting booklet now. Fill out the coupon printed here for further con- venience, and mail at once. Address Bleadon-Dun CO, Dept II, 11 So. Desplaines Sts., Chicago, Ill. For this interesting booklet about the Violetta and ten days' trial offer.

GRAND OPERA IN YOUR HOME.

(Continued from page 855)

microphone circuit could be loaded simultaneously with such an immense number of lines as this practice constitutes a short circuit, and while the thing is possible in a limited way by means of induction coils, nothing less than two or three hundred subscribers could be linked up by such means. Therefore, the system herebefore was a failure.

The invention of the Audion, however, has changed this and by using audions to "boost" the circuits, it is now possible to connect a practically unlimited number of listeners to one microphone transmitter and reproduce the music clearly in 50,000 homes at the same time.

The writer who interviewed high telephone officials was informed that the plan was entirely feasible and there was only one objection, which is not of a technical nature. It rather has to do with the advertising factor. Thus, the telephone engineers did not think it good business to tie up say twenty thousand to fifty thousand lines simultaneously for several hours at a time on account of the congestion that would probably ensue, but this is really only a small consideration and not of much importance if the enormous revenue that the companies will derive from this scheme is taken into consideration. While the subscribers now pay only between two and five dollars a month for service on an average, the telephone company could easily double this revenue for at least 20 per cent of all of these subscribers by installing the operating service.

Today the man who owns a phonograph thinks nothing of spending between three to five dollars a month for records which are "dead". If he knew he could hear Caruso, Galli Curci or any of the other stars tonight in one of his favorite operas, he certainly would object to spending 50 cents or even a dollar for the privilege, and that he would want he was getting it cheap because he, with his entire family, would hear the music in his own home, without having to travel to and from the opera house. Eventually, if the system should become vogue, the opera alone will not be the only source of amusement to be drawn up by a telephone subscriber. Any of the musical plays or comedies, farces, etc., could all be heard over the telephone, altogether admitted not to such an enjoyable extent as grand opera, where it is the music that counts most.
As for the technical aspect, we now have very good sensitive microphones, which place a great deal of the work upon the stage and orchestra; the orchestra is not needed. The microphones are then connected to the auditorium or home. The orchestra is not needed. The microphones are then connected to the auditorium or home. The orchestra is not needed.

Here we have a novelty suggested by the writer. In transmitting music over the telephone before, it was not possible for more than one member of the family to listen to the music as there was only one telephone receiver. By means of modern loud talker telephones, however, it now becomes possible to lift off the telephone from the hook and place it over a sensitive transmitter, as here illustrated. The sounds picked up by this transmitter are strongly amplified and projected from the horn in great volume. Thus, it becomes possible for any one in the room to hear the music clearly and as loud as we do sitting in one of the farther rows in the theater, where the hearing is not always good, as is well known.

As for the subscriber's amplifier as shown in our illustration, this may be made of the ordinary loud talking variety, having a simple hyper-sensitive microphone connected to a loud talking telephone, or otherwise it may be a microphone connected to an audion amplifier. The latter probably is the better of the two systems.

The amplifying cabinet can be hung over the telephone, in case of a wall set, or otherwise it can be set in a different shape for table use if the telephone is of the portable type. The amplifier could be sold outright to the subscriber or otherwise rented to subscribers by the telephone companies.

We feel confident that a plan similar to the one outlined here will soon come into general use, as there is a positive demand, particularly in America, for good music and which demand as yet has not been satisfied.

But like all other large interests, the telephone companies are slow-moving organizations and do not make innovations unless they know that a large part of the public actually wants them. Therefore, if you are in favor of this plan, we think it would be a good idea to write the headquarters of the telephone company, advising them what you think of this plan. If, however, you were to write to your local telephone company, not much impression would be made. If, on the other hand, you address your letter to the American Telegraph and Telephone Co., No. 35 East St., New York, then there is a chance that a national movement would perhaps result from such letters. Local telephone companies cannot maintain their present standards if they are governed by the policy which originates at the New York headquarters. Perhaps your letter will help to bring the Opera into your home.

TELEPHONE GIRLS' WORK IN FRANCE.

It is difficult for us to realize the scope of the work that has been done and is still being accomplished by the telephone operators in France. To serve the needs of an army of two million men, and in addition an army that now has the French by telephone was a mission that required no small amount of organization and planning. On the part of the Signal Corps, says the Telephone Review. The distribution of the girls in the Signal Corps service asked for careful study and met with unqualified success.

EXPERIMENTAL PHYSICS.
(Continued from page 867)

HOW AIRPLANES FIND THEMSELVES BY RADIO.
(Continued from page 871)

"The use of directional effects of loops or coils for receiving radio signals has re-
sulted in the development of a radio compass for airplanes which gives positive in-
formation to the aerial navigator and en-
ables him to locate his position by triangulation with regularity to within a few
land stations or to fly at any given angle with respect to a certain beacon station.

The apparatus consists of two principal parts—the antenna coils and the tuning and
amplifying apparatus. The antenna coils are mounted in the fuselage of the Handley
Page airplane, with suitable means for rotating in azimuth. The amplifier is ex-
tremely sensitive, consisting of a detector and six-stage amplifier. A novel feature of
the amplifier is the use of iron-core trans-
formers for frequencies of 100,000 cycles.

The direction of the beacon land radio
station is determined by maximum strength
of signals, in a highly ingenious manner de-
veloped originally by the British. The pre-
cision of the directional effect is remark-
able. Fact, the radio direction finder may well be called a radio eye."

to send and take messages in spite of
the enemy's interference by sending out im-
pulses of similar wave length and other
disturbing influences. The problem of
using a non-inflammable gas for inflating
balloons and dirigibles has been solved un-
der the direction of a Physicist and a Chem-
ist, both "fool professors".

The submarine has probably attracted as
much attention of the scientific men
as all other war inventions combined, both
as to its detection and its destruction. The
detection of the submarine is a purely
physical problem, and it is estimated that about
one-fourth of the Physicists of the Allies
have devoted a considerable portion of their
time to solve this problem alone. The prob-
lem has been attacked from three stand-
points, light, sound, magnetism and elec-
tricity, three branches of work which almost com-
prise the entire subject of Physics. The de-
struction of submarines has been success-
fully accomplished by the use of the depth
bomb.

In long range artillery work, temperature,
misture, and wind are to be carefull
determined; this is done by physical appa-
ratus. Wind direction and barometric pres-
sure information is essential in a gas attack.
This information is furnished by physical apar-
tatus. Anti-aircraft gunnery is largely in-
depted to physical research and calcula-
tions for its effectiveness. The speed of the
airplane must be ascertained, its direction
of motion, its height above the ground, the
speed of the attacking shell, and its path.

The airplane camera would be almost use-
less were it not for our knowledge of the
branch of Physics known as stereoscopy.
Pictures can be taken which the eye can-
not see because of fog, cloud, haze or dis-
tance. By the use of special glasses the
enemy's guns camouflaged so as to be in-
discernible to the eye, are photographed and
their positions located. The sound method
of locating an attack is not as effective as
the three sounds are heard from a shell sent
by the enemy. First we hear the hissing noise
of the shell whizzing thru the air. Shortly
afterward the boom of the gun is heard. (Since
sound travels at about 1,100 feet per
second and the shell's speed is greater than that), Finally we hear the sound of the
explosing shell. If the time when the first
of these three sounds is heard is recorded
at several observing stations, from the speed
of sound, and the difference in the times
recorded at these stations, the position of the

ELECTRICAL EXPERIMENTER

A TIMELY REINFORCEMENT.
A Copper Plated Stomach.
(Continued from page 87)

thanks to mother and the salt fish—and the cat.

You have to begin by discarding the whole idea of sheet copper. It would be all right, and a little bit more, if you make up a good tummy in half a day—even including going back to the shop for his tools—but for the fitting of it, or inserting, or whatever you'd call it, a sticker; it's what's kept the invention back all these years.

But why not plate the copper on from the inside? Sure! There it was, right off the bat!

Fig. 1 shows the invention—patents pending—all worked out—perfectly simple. You procure an atomizer, A, and attach to it a long fine rubber tube, B. This tube is surrounded by a spiral wire, C, and both are covered by high-tension insulation, K. At the further end both the tube and the spiral wire are connected with the perforated metallic hollow sphere, E. The atomizer-bottle, F, is filled with a solution of sulfate of copper, and the spiral wire is connected with one pole of the spark-coil secondary, H. Around the patient's waist is then bloused a strip of wire netting J, connected with the other pole of the spark-coil.

All being done, the patient "swallows" the perforated ball, E, with enough of the tube to maintain communication with the outer world. The ball is then resting nicely into the cozy little hole, and the patient closely; a really delightful surprise is about to be handed to him? X! Pressure on the button is all that is required of copper sulfate from the perforations of the sphere, E, while at the same time a touch of the key, L, causes a shower of sparks to be thrown from the ball toward the metallic belt without. The sparks pass easily thru the patient's tissues, but not thru the sulfate. This is decomposed by the electric current, and metallic copper is deposited on the gas- tric lining, forming a dense and highly polished surface, ready to tackle any food product short ofians—red-eye and Irish confetti—brick-bats.

Perhaps you wonder why, before the operation, the patient took a few magnesium pellets, too, before applying the "fever saver"? This was to take care of the other product of the reaction, sulfuric acid—otherwise the ball would be well on its way to death as the way he is. The magnesium neutralizes the acid, producing a pleasant effervescence, which, being flavored by the copper, is not unpleasant, though the equivalent of an ice-cream "sody" fresh from the fountain.

So behold! At the end of the operation, when the patient finishes his cigarette and lets go the nurse's hand, there he is,—equipped with a perfectly-fitting copper stom- ach—each atom of which has been used as a hint to guide him in the selection of future contents for it—like a new tin bank for little Willie, with a dime in it.

No, no, no said that metal. Really I—well, if you must, you must. But I refuse to patent the idea in Germany. Absolutely. It's just limited to the free use of all free and civilized countries. "That's me all over—liberal, Mabel."

"Not so, the editor tried Tom's latest stunt. After he was granted his patent, and was at last equipped with his copper "insides," he felt pretty weak. So he lamped himself up into a bird of zinc dust with his next meal. The copper tummy, the gastric juice,—(an excellent electrolyte)—plus the zinc dust, makes a really excellent battery. Tom received the editor at once. It works so well that he has given up all food in preference to zinc dust. A slight change in diet is had with magnesium dust—it tastes better, and gives a much higher voltage. Iron filings were tried, but they made the editor "ratty!"

Learn Drafting

Employers everywhere are looking for skilled draftsmen. They are offering good salaries to start with splendid chances for advancement.

Drafting offers exceptional opportunities to a young man who desires to make his living entirely as a draftsman. A man with qualifications necessary for success in Mechanical or Structural Engineering or Architecture. And drafting is just the kind of work a boy likes to do. There is an easy delightful way in which you can learn right at home in spare time. For 25 years the International Correspond- ence Schools have been giving boys just the training they need for success in Drafting and more than 200 other subjects. Thousands of boys have stepped into good positions through I. C. S. help, but never were opportunities so great now.

Let the I. C. S. help you. Choose the work you like best in the coupon, then mark and mail it. This doesn't obligate you in any way but will bring you information that may start you on a successful career. This is your chance. Don't let it slip by. Mark and mail this coupon now.

The Alkaline Storage Battery

(Continued from page 878)

Consequently the engine would have to be operated at various rates and at all times. This is uneconomical. By using a storage battery one may arrange to run the engine at its most economical (full load) rate and thus effect a saving to offset more or less constant current losses, current resulting from the use of a storage battery between the generator and the lights. Further, the storage battery tends to improve the character of the steadiness of the light. With a small installation where the current passes directly from the dynamo to the wires supplying the latter, and to manifest undesirable fluctuations in brilliancy because of irregularities in the running of the engine. By using a storage battery one is able to use this fluctuating current in charging and then to get an even current from the battery.

A shunt-wound dynamo is the thing to use--else, when the voltage of the battery rises too high, it may "back up" and oper the dynamo (series type) as a motor, causing considerable damage. If a compound wound dynamo is already installed, or if it is desired to use such a machine for charging storage batteries, it can be done simply by making additions to the terminals, so that the field coils, thus converting the machine into a shunt dynamo.

The dynamo which is used to charge a battery should always have an excess voltage capacity. Thus, if we are going to use a battery of 30-32 volts rating, it is good practice to employ a 45-volt dynamo for charging. In fact, we may largely consult convenience when charging a battery, provided the correct rubber cap is next lower one. A 110-volt dynamo may be employed, at times, for charging a 30-32-volt battery, thru a suitable resistance; the perhaps the correct voltage of a dynamo.

The alkaline battery with which we are concerned is made up in a variety of sizes, of which that known as "A" is quite popular for electric automobiles and trucks. A numeral used along with the letter indicates the number of positive plates used in the cell. These numbers furnish a rough gauge by means of which the comparative capacities of the type of cell may be determined. The reason underlying this is that ampere-hour capacity is in proportion to the total area of plate and to the surface exposed to the action of the electrolyte. An A4 cell will have about half the capacity of an A8 cell, etc.

Charging.

The positive terminal of the battery is connected with the positive line of the supply current; and the negative terminal with the negative line. The positive pole of this type of cell is indicated by a red bushing, and also by a + mark stamped in the metal of the container. A black-bushing is used for the negative pole. A further means of distinguishing the positive and negative poles is by means of the form of the little contain- iners in the plates. The round tubes below the plates, and the flat pockets to the negative plates. If substan- tial heating is noticed at or near a cell pole during the charging operation, it is to be taken as an imperfection in connection. If, however, all the connections are tight, then disconnect and determine what is the trouble. The proper charge for the metal contacts are flat and rigidly clamped.

If there is any doubt as to which is the positive pole, the method is to look down the tube, and if the wire, the following simple test is recommended—Connect one wire of the generator with some form of resistance. The free end of the unconnected wire from the generator may now be brought close together in a cup of salt water. In a moment one wire end will begin to turn bright. Bubbles will form at this wire. This is the negative one. The other is, naturally, the positive wire.

Normal Amount of Electrolyte.

The proper amount of electrolyte is such that plates will be 1/8 inch below the surface. If the level of electrolyte is too high the weak is likely to create a transient level. Tests for the level are to be made after the charging is all com- pleated and the liquid has settled down. As it may not be easy to see conditions inside the cell, a good way to determine the depth below the plate is to use a piece of straight glass tubing with a bore of, say 1/8 inch or more. Introduce one end of the tube, holding it vertical, until the bottom of the tube is on top of a plate. Then close the top of the tube with the forefinger and withdraw the whole. At the point the bulb of the electrom will be in just below level whose height will be the depth of the plate top. When the right amount of electrolyte is in the cell, the level of this col- lumen is said to be 3/4 inch. Simply a glass tube is required. No rubber cap or tube is needed in addition and the tube of an ordi- nary fountain pen is used. The rubber bulb is removed and the larger end of the tube is inserted into the electrolyte.

The operation of charging, as already intimated, involves the production of gas. Some, at least, of this gas comes from the decomposition of water in the electrolyte. If the charge is sufficient, many gases will naturally be lost, and the result will be a slight reduction in the total volume of the electrolyte in the container. Consequently, the proper time for height of the solution is subsequent to charging. The remedy for this loss and any other loss due to withdrawal of water (as, for example, by natural evaporation) is the addition of pure water.

Adding Water.

When water is to be added to the con- tained electrolyte to bring the surface to the required height or to correct a solution which has become too weak, gas should be employed. Only distilled water is to be used, as the method is by means of introducing it. Of course, do not add water during charging, for the reason that the level can not be exactly determined at all times, as already pointed out. The addi- tion of water will not, ordinarily, be re- quired every time the battery is used. Usu- ally, once or twice a week will be sufficient, unless the operation of the battery is very considerable. Other things being equal, water will be necessary oftener when the constant current method of charging is used instead of the tapering current method.

Two Methods of Charging.

To charge by what is known as the constant current method the rheostat is set a few amperes higher than the current it is proposed to deliver. The amperage will fall off as the charge is taken up, but by readjusting the rheostat every 30 minutes or so to a point somewhat higher than the reading of the ammeter at which it is maintained. To charge by what is known as the tapering current method, the rheostat is set a considerable amount above the desired current per cent, and a current delivered without further adjustment. At the end it is proper that the cur- rent should be considerably below the aver- age. An advantage of this method is the relief from attention during the charge.

LISTEN TO ME!

Be a CERTIFIED ELECTRICIAN

THIS IS YOUR CHANCE OF A LIFE TIME

I am Chief Engineer of the great Chicago Engineering Works. I am in close official touch with the electrical world. I know how badly we need trained electricians who can take charge of important work as experts. Right now there is such a need for executive electricians that I am making a special effort to help meet the demand. I am publishing this special an- nouncement to secure a certain number of ambitious men whom I will personally train by mail for the wonderful opportu- nities that are open.

I WILL MAKE YOU a Trained Electrician

I don't care how young or old you are, just as long as you can read and write and have a spark of ambition. I don't care where you live or what you do. I don't care if you don't know a blessed thing about electricity. Just give me a little of your spare time for a short period and I'll show you the quick way to success in electricity. You can qualify to earn $35 to $100 a week with opportunities for greater earnings.

I Train You by Mail!

Your spare time will do. No interfer- ence with your regular duties. I under- stand just what you must know and I have devised a wonderful way of instruct- ing by mail. I positively guarantee your satisfaction.

Free Wonderful Electrical Outfit

Absolutely free. Not a penny cost to you now or later. To those who act at once I will give a wonderful set of Elec- trical Equipment with my compliments. Write me at once. I have only a limited number of sets to be given free. Drop me a post card or letter.

Write! You will have to act quick to get in on this opportunity. Write me today for particulars. Drop me a post card. Write Now.

Continued on page 934
You can easily make a highly sensitive deteetophone by using a Skindervenik Transmitter Button to collect the sound waves.

You can build your own outfit without buying expensive equipment. Think of the fun you would have with such an instrument! It's very simple, too, and inexpensive.

You can install an outfit in your home and hear the conversation being held all over the house. You can connect up different rooms of a hotel. Our outfit was used by secret service operatives during the War. It is being used on the stage. So much for its commercial adaptations! You can procure apparatus of the same type.

One of the main advantages of the Skindervenik Transmitter Button lies in its ultra-sensitivity. You can place it in any position you like. It is the greatest invention in micro-phones and has recommendations from men of high standing in the scientific world. It is being used all over the world. You can mount it most anywhere. In figures 3, 4 and 5 are shown some unusual and practical methods. Cardboard boxes, stove pipes, stiff calendars and hundreds of other places will suggest themselves to you. The buttons cannot be seen by any one in the room as they are so small and light. Only a small brass nut is exposed to the view.

Full directions for connecting up the button for use as a deteetophone are given in booklet No. 4 which is sent with each button. Figures 1 and 2 of this advertisement, two of the many illustrations in booklet No. 4, show the circuit connections of the deteetophone. The only instruments needed to complete a deteetophone outfit, in addition to a Skindervenik Transmitter Button are a receiver, battery, and, if desired, an induction coil.

Among electrical experimenters the button has created a sensation. It is not uncommon to receive unsolicited letters like these: "I received transmitter button today and I wish to inform you that it works great and is the best I have ever seen or heard of for the price. I will certainly keep it to my friends. I wish to thank you for your good service."

"I have been using one of your transmitter buttons, and it has proved to be worth more than its value in my experimenting." "I received one (Transmitter Button) some time ago, and they are just O.K. for experimenters. I have been using one of your transmitter buttons for experimental work and it certainly lives up to all you say for it and some too."

Mr. H. Gernsback, editor of this magazine, who is the dean of electrical experimenters, said: "In my judgment the button is probably the most efficient device of its kind on the market today, due to its extreme sensitiveness and other outstanding features. Should have a great future."

Figures 6, 7 and 8 suggest some very interesting experiments. That of reproducing music at a point far removed from the phonograph is very popular with experimenters. The Skindervenik Transmitter Button is mounted in a very small hole in the under side of the sound arm. (Note: There will be no injury to the performance of the phonograph). When the phonograph is being played, the sounds produced are transmitted by the Skindervenik Transmitter Button into a varying electrical current. The receiver, which is mounted in another room, reproduces the music at that point.

Figures 7 and 8 illustrate the methods of transmitting sound by means of the vibrations in a body while speaking. Speech will be reproduced by the receiver just as if the experimenter had spoken into a transmitter. In these experiments the Skindervenik Transmitter Button is mounted on a small iron disc. The same circuit connections apply to all experiments, regardless of how the transmitter button is mounted. The Skindervenik Transmitter Button operates on one or two dry cells. It often happens that two cells produce too much current and the sounds are deafening. We recommend either one new cell or two worn out cells.

We have the utmost faith in our transmitter buttons. We guarantee satisfactory service or we will refund the purchase price. Boys—Young and old—send in a dollar bill RIGHT NOW! You can't lose. If you're not satisfied, you receive your dollar back, isn't that fair?

Send a 3c stamp for a copy of Booklet No. 4.
